Mr. MAGEE: This specimen here is one of the cases of intussusception I refer to in my paper. I must apologise for not producing the second specimen of this condition. It has got mislaid.

#### *Forceps.*

This instrument is Hobday's bitch forceps which has also been mentioned in one of the cases reported.

CHAIRMAN: You have heard Mr. Magee's account of these interesting specimens. We would like to hear some remarks upon them.

Mr. MAGEE: Mr. Chairman, before any discussion takes place, with your permission I would like to say we have with us this evening a member we have not seen for a long time—Capt. Winter, and on behalf of all present I bid him "welcome back." During the last four years I am sure he has seen a good deal of life abroad and had many interesting experiences, and, time permitting, I would like him to tell us some of his adventures in the veterinary world.

Capt. WINTER: It gives me great pleasure to be amongst you again. I am sorry that my absence has hurt the other association to which I belong, owing to my not having time to resign my position formally. But I hope to remedy that and get it into life again. I think friendly rivalry helps a good deal.

As to these specimens, I think they are particularly interesting. I have lively recollections of a case of choking with a potato, but in my case the potato had been boiled. I could touch it with my finger, but nothing more. I could not get hold of it with a corkscrew nor put it down. Finally I got it away by getting the assistance of a man to push against me until I got behind it. It was the hardest hour's work I had in my life. Mr. Magee's communications are very interesting, especially the case of intussusception in the dog. His case of a foreign body is also interesting. At first sight I thought it was a tapeworm, but it would be a long one.

About the amputation of the sow's organ, I had two or three cases like that with different animals, and I think it is the only thing to do when you get the uterus badly damaged. It is not a formidable operation and as a rule results satisfactorily. I have done it with a mare and a cow. The mare will kick and otherwise injure the part, and the smaller animals will walk on it. If you get rid of the whole thing from the neck and get a clean wound, and get it back into the vagina, the result is generally favourable. The whole thing is to get it done in time.

I had one or two experiences of horses being "set," and got them "put over" on me too. I knew intimately an old man who undoubtedly could set a roarer or a whistler and he tried me "pretty high" once or twice. He did me once, but I got him twice afterwards by turning up unexpectedly. These cases would be alright for about 24 hours. I have examined a horse at his place which I knew to be a whistler and had to pass him, but two days afterwards he was a whistler again. There was nothing whatever that I could detect. I would give a good deal to know what he used, but he never told me nor anyone I know of. Of course if you see a horse "dopey" you are not always at liberty to put him back for a day until you communicate with your client. Undoubtedly that practice is dying out in the country, but it used to be very common when I started practice.

As to the newly born foals, there is no question that they are very liable to constipation, and in a good many stud farms it is customary to give a foal an injection of linseed or castor oil immediately after it is dropped, and with very good results. I prefer linseed myself. That generally obviates the trouble, a good many farmers used to pass a tallow candle into the rectum.

Mr. HEALY: A glycerine suppository beats that. You can't get tallow candles now.

Capt. WINTER: There are a good lot of old customs practised amongst farmers which had a good deal in them.

The cases of these thoroughbred horses were rather peculiar. We come up against such cases now and again. I should think they were cases of poisoning of some sort—probably by the fungus suggested here.

These cases are very common all over America, and the subject there has not been fully threshed out, owing to the districts being thinly populated and the difficulty of veterinary surgeons getting round the country. The profession however is progressing there. A good deal of that is due to the activity of associations, the membership of which is growing. I had the pleasure of attending two or three meetings of the American Veterinary Association and they were very interesting. The only objection I had was that everywhere I went I was asked to give a "talk" and some of the remarks were very caustic. I introduced one or two things which I thought were good. One was the Rig operation, which I had done. Some of them were very sceptical, but they could not get a case to operate on. However, they found me an old mare and I removed her ovaries in the same fashion, which was almost as satisfactory as taking out a testicle. One member said he had been doing abdominal operations for a great many years and never had a death. My observation on that was that in my country we would think that extremely lucky. (laughter). I do not think there is anything more interesting, and which promotes discussion amongst members more freely than notes on clinical cases, and the production of specimens like these. They are the result of every-day practical experience, and I think they are very interesting. Later on probably I may be able to relate some of my experiences on the other side of the water, when I get them together in a more concise form.

Concerning the two horses, it struck me when I read these cases that it is quite possible it may have been sorrel poisoning, and if the place is any way near at hand, it might be worth Mr. Magee's while to walk round and see if he will find any sorrel in the clumps. I think vegetable poisoning in both horses and cattle is much more common than is thought.

Mr. WILKINSON: I have to thank Mr. Magee for his interesting and candid paper. We have had very few papers like this that admit deficiencies. As to the sow, I would like to ask did he put on one ligature only, and what became of the ligature eventually? [Mr. Magee: Just bring it round and knot it, it sloughs away afterwards.] I think that forceps for concretions in foals is a good suggestion. Like Mr. Healy, I have used glycerine with good results. It seems to be very powerful, and acts satisfactorily.

I remember one case of obstruction in a dog, which I was told had not passed anything for a fortnight, at any rate the animal suffered considerable pain. I examined the rectum and found a piece of thread hanging out, and when I tried to draw it out it gave the dog excruciating pain. On putting my finger as far as I could reach I felt a needle embedded top and bottom. Finally I got rid of it after very considerable difficulty by introducing a scissors and cutting the needle in two. [Mr. Magee: Had he swallowed a needle?] He must have. It was across the rectum, and you could not possibly pull it out. The thoroughbred cases seem to me to be narcotic poisoning. You don't mention if there were any other horses. [Mr. Magee: There were only two horses, but there were cattle on the land.] I have read some accounts in *The Record* of poisoning from ragwort. It just occurred to me there might have been some of that about.

Mr. MAGEE: You must remember there was a botanist in the case.

Mr. HEALY: I have to thank Mr. Magee for the practical paper we had from him and also for the specimens he has shown. I would only like to refer to the "setting" of horses. I remember one case which occurred at the

Dublin show. There was a big chestnut horse examined for its wind by the late Mr. John Freeman. It was sold for a long price to a member of the profession, Mr. Henry Withers, of London. Mr. Freeman who was examining the horse beckoned me over to him while galloping the horse for his wind. I got the aroma of chloroform from him, and drew Mr. Freeman's attention to it. He adjourned his examination for two days; on the third day he was the worst roarer a man could hear. That horse had been "set" with spirits of chloroform. For the "setting" of a broken winded horse, the old tinker treatment of shot and butter is one of the best. I remember seeing a case one time with Mr. Ashe of Cork, when coming from the fair of Bartlemy, a horse dead in a dyke. The man who had bought the horse hailed him, but Mr. Ashe said nothing could be done for the horse, and that he should be taken to the kennels. We went to the kennels the next morning and opened him, and found about 60 or 70 pellets of swan shot—old fashioned bullets like you would make for a catapult—and the stomach was badly ruptured. He had been examined by a practical dealer and passed sound of the wind.

Mr. WILKINSON: I had an instance which happened in my own practice within the last six weeks. I was asked to examine a very fine draught horse, and the man remarked to me afterwards "If it is wrong in its wind, it is not your fault." Three days later the horse came in to be shod: I was in the office, and I heard a most suggestive cough. I went out to see the horse and here was the lovely animal I had passed sound three days before. He had the characteristic heave and cough of a broken winded horse. The man said they had a week's agreement, and the horse was sent back. I saw the horse about three days afterwards and he was perfectly well—no sign of any heave at all. I did not gallop him, but the thing was so patent before that an amateur would have noticed the difficulty in breathing. There was no suggestion that the horse had been "set." One of my friends told me he had met a case of it and he had attributed it to spasmodic asthma.

Mr. DUNLOP said: I am sure we are all much indebted to Mr. Magee for giving us a paper and producing, on short notice, such interesting and unique pathological specimens. He had always entertained the idea that broken wind was a chronic form of asthma, the result of continued congestion and thickening of the lining membrane of the minute bronchi. In aged or middle age horses very special care should be exercised in testing for broken wind. The cough, especially after galloping and a drink of water, is a good criterion, and he thought a few whiffs of sulphurous acid gas might be had recourse to in doubtful cases. He never could understand why shot should be used to set the wind. Shot is not only dangerous but the lead dissolves too slowly in the stomach to have any medicinal effect. He thought, for setting the wind, it would be hard to beat Professor Dick's formula, a dram each of calomel, opium, and digitalis. He had on several occasions had his attention directed to the wonderful curative effects of a combination of some mercurial preparation with digitalis, squills, and certain salines as used in the human subject by some eminent physician. The effects were most marked in clearing out the smaller bronchi and as an absorbent in cases of schirrous liver.

So you see there is some similarity between Dick's formula and up to date medical treatment. Needless to say it is of primary importance in treating such cases to remove the cause, and to attend to dieting and scientific ventilation (not fresh air, which usually means draughts.)

With reference to union of the fractured femur by overlapping, it is surprising what nature does sometimes. He had a dog brought to him by a lady. The dog had

a fracture of the neck of the scapula, the result of a kick from a horse. He first applied thin gelatine on the hair over the scapulas, then he applied a bandage in the figure of 8 fashion. He then used a suitable thin splint extending from near the top of the scapula to the elbow. Another figure of 8 bandage with gelatine was applied over all. The dog seemed quite comfortable after the bandaging and continued to hop about, until one day he went into the water for a swim and left bandages and splint behind. He evidently found they were no longer necessary.

Mr. LAMBERT: I have great pleasure in complimenting Mr. Magee on his very excellent paper. I would like to make a remark about the golf ball. I came across a similar case in a dog. The core of a golf ball is very small and hard, and when it gets into the stomach opens very easily and gets just like the specimen produced, once it comes in contact with any wet. As to the "setting" of the wind I have come across several cases where men have bought horses and told me they had been driving them the day they bought them and they were perfectly alright, and the next morning they found them badly broken winded, and came to get a certificate so that they could return them. I never could make out how they were "set," they were so badly broken winded. As to choking in cattle I would like to ask if he had ever tried arecoline in these cases. I always like to take my time over a case I cannot manage easily, and have always found arecoline very successful. As to the fracture of the bone, it is a very common occurrence, and I have seen fractures very similar to that one. I have held any amount of post-mortems on dogs with jaundice and found intussusception but not in every case. I have seen hundreds of cases of puppies with intussusception without jaundice. I don't think it is necessary to have intussusception in jaundice at all.

Prof. CRAIG: I have read with very great interest the paper which Mr. Magee has prepared for discussion at this meeting and I am glad he has brought forward these valuable specimens to demonstrate the conditions which he has met with. The cases he records are well worth discussion and in some of them there is no unanimity of opinion as to the cause of the condition. There are a few points which struck me in reading the paper and listening to the further clinical cases which he has described.

As regards the two cases of jaundice with intussusception I cannot agree with his ideas of cause and effect. Cases of jaundice in dogs are not uncommon in this country, and their causation has not been ascertained. They have been referred to as cases Malignant or Epizootic Jaundice. They have been seen in kennels where distemper is prevalent, but their connection with distemper is not apparent. I have examined a number of these cases. There are no piroplasms in the blood. The jaundice is not due to catarrh or any pressure upon or obstruction to the bile ducts. The bile may be easily pressed at a post mortem examination from the bile ducts into the duodenum. The jaundice in this case is probably bacterial or toxic in origin. In some instances I have noted, like many others, intussusception of the bowel at an autopsy, but I think that the intussusception occurred during the last stages of the disease. Unless the telescoped bowel involves the opening into the bile duct, it is unlikely that jaundice will follow. I therefore take it that the intussusception has followed upon the jaundice. Trasbot in some experiment ligatured the intestine, but the ligation was not succeeded by jaundice.

With regard to the question of broken wind, I think our knowledge of the pathology of this disease is yet in a state of chaos. We speak very glibly about broken wind, but we don't know exactly what is the cause of the condition. It is usually referred to chronic vesicular

emphysema of the lungs, but I question very much whether that condition accounts for the symptoms we associate with the disease. I have examined cases where the post mortem examination revealed very extensive emphysema and yet these horses had shown no symptoms of broken wind during life. On the other hand, I have examined the lungs of some horses which were broken winded and yet very little emphysema could be detected at all. Possibly there is more than one condition described under the heading of broken wind. Some of the cases probably are cases of bronchial asthma. No doubt we try to distinguish some of them by the cough but it is the temporary reappearance of the symptoms which is of the greatest diagnostic value. I have no doubt that it is these instances some people have been wrongly accused of doping. That the drugs which have already been referred to as well as others are of value in moderating the symptoms of broken wind or giving temporary relief rather indicate that there is something other than vesicular emphysema to account for the condition.

With reference to the case of West Indian and Rodney Stone, I cannot offer any definite opinion as to the cause of the trouble. I think I have seen two cases of the kind, one in a donkey and one in a carthorse. The usual history which precedes haemoglobinuria was not present. Both were in good condition and were fed in the house and in addition were receiving the same diet as some other animals. The urine of these two was like that of coffee and I thought they were affected with haemoglobinuria. Both animals died after a short illness. In neither case was there any nephritis and I could find no muscular lesions such as one expects to meet with in haemoglobinuria.

Possibly the cases Mr. Magee describes were caused by some obscure form of vegetable poisoning. We do not yet know whether at certain times or under certain conditions some of the common plants may acquire poisonous principles. In view of recent investigations it is quite probable that this may occur, and an ordinary chemical analysis give no indication of the presence of the poison. It has been suggested that sorrel may account for the condition. I think that the poisonous action of sorrel has yet to be thoroughly investigated. We know that in France and Canada there is a haematuria of cattle in which the experimental evidence goes to suggest that the cause is an excess of oxalic acid in the food, but the cases are chronic. They are not at all comparable with those that Mr. Doyle has spoken of or those described in the paper. I may say here that I have come across a few cases where the history and condition of the urine points to the occasional presence, in some parts of Iceland, of a disease in cattle similar to that described in France and Canada.

I am glad to hear that Mr. Doyle has been so successful in his treatment of the affected animals, whether they were cases of sorrel poisoning or not. The specimen of white hairs which Mr. Magee removed from the opening of the prepuce in the ox I have examined and I note that the colour is due to the deposit of lime-salt upon the hairs, no doubt coming from the urine.

Mr. NORRIS: I speak with considerable diffidence upon clinical matters, as it is now some years since I have been engaged in general practice. I am, however, greatly interested in the cases and specimens which Mr. Magee has so kindly provided for us. The case of the sow seems to be another illustration of the insusceptibility of the pig, to shock and septicæmia. As to "wind setting" I have very little experience, but I am inclined to agree with Prof. Craig, that all such cases are not cases of Emphysema of Lungs. Some of them may be "Spasmodic Asthma"—whatever that may be. The deaths of the two horses are puzzling—but very interesting. Mr. Magee and other speakers are inclined to

attribute the deaths to some form of vegetable poisoning, and this view of the case I support. Sir S. Stockman has shown that some plants,—commonly regarded as harmless, may by cumulative action cause death, and it is just possible something of the kind may have operated in these cases. The recent work on the subject of plant and forage poisoning shows there is a great field for further research upon this subject, which, apparently, has been too long overlooked.

Mr. CUSHNAHAN: I have to thank Mr. Magee for bringing before us such important subjects. I remember some years ago a similar case of eversion of the uterus coming under my notice. The eversion had been in existence for some short time, and the uterus had become more or less tumefied; I saw no course to adopt other than excision. I passed a double ligature through the neck of the tumour and removed the uterus. Of course, I was fairly satisfied that no abdominal viscera was included in the eversion. These cases are rare, and I have not seen any in recent years.

Broken wind is a very important subject because it is really a veterinary legal matter—at the present time cases come into the courts where veterinary opinions are conflicting. Mr. Wilkinson mentioned spasmodic asthma; I remember a short time ago a practitioner who has a large practice in the examination of horses told me that he had examined a horse and cast him for broken wind. Later, when he saw this horse he considered him sound. He had no doubt it was a case of spasmodic asthma. In my opinion broken wind may be due to spasmodic asthma or to emphysema: the latter is usually accompanied by hypertrophy of the heart. When I examined horses years ago, I was pretty well satisfied with the character of the cough; I never troubled much with "heaving" or "double flank action." I remember on one occasion having examined a horse, and after a stiff gallop I was almost satisfied he was right; but after coughing him I was convinced he was "broken winded." Whether this horse was "set" or not I could not say. Lead has been spoken of as the usual agent for this purpose. It may have a mechanical action, and cause relief for a time; or it may have a physiological one through the nerves.

The death of two horses mentioned by Mr. Magee interests me particularly. It has opened up a wide field so far as the diagnosis of intestinal trouble is concerned. I have seen many cases of death due to colic when the post-mortem did not help us out as to the cause of death; all the organs were perfectly normal, and we could not find even a trace of congestion in stomach or intestines. As to vegetable poisoning, a good deal has been written by experimenters in many countries. Sir Stewart Stockman must be regarded as the foremost experimenter in these countries. Whether death in all cases of vegetable poisoning is due to toxins is hard to say. Some may act by causing impaction; we all know that in a horse affected with stomach staggers the condition is due to toxin in rye grass at a particular period of "seed-ing"—I think it is an accepted theory that this condition is due to a toxin produced in the new hay immediately after it is cut. I have seen many cases, and the symptoms shown were undoubtedly toxic. I have also seen similar cases occur in cattle during dry seasons. These were usually attributed to indigestion, but I regarded them as toxic. Recently I have read a paper by Professor Graham of the department of Animal Pathology, University of Illinois. He, with others, has carried out experiments with regard to poisoning by certain cereals. At the Kentucky State Veterinary Department they found in oats a bacillus resembling in all respects the *Bacillus Botulinus*. Professor Craig says that probably the toxin may have been in the plant, but Professor Graham and his colleagues satisfied themselves that death invariably occurred in the cases experimented on through feeding animals on organisms recovered from

the oats taken from the different farms. Horses and mules were used in the experiments, and feeding them with drinking water contaminated with these organisms produced death. Another interesting matter he mentioned was that they treated ruminants from these cultures and produced an anti-toxin serum. This seems to open up a new field of research. It may have a good deal to say in the future in the treatment of colic and intestinal cases.

These cases of vegetable poisoning are well worthy of consideration—whether the toxin is elaborated in the plant itself, or due to saprophytic organism on the plant. Seeing that valuable animals die from obscure causes I think that such deaths are worthy of investigation.

Mr. Magee's communications are always full of interest, and I have to again thank him for bringing these forward for discussion.

Prof. MASON: I have been experimenting with methylene blue through the whole of Ireland in the treatment of contagious abortion, and it is quite possible some person has been using it as a remedy for abortion and promiscuously used it on all his animals, and that would account for this blue hair. With regard to vegetable poisoning, when Mr. Doyle was ill some time ago he asked me to look after a few cases for him. His qualified assistant asked me to look at some cases which he took to be red-water. I knew Mr. Doyle was particularly interested in this matter of vegetable poisoning, and I did not agree with his ideas. I treated these cases as being red-water and failed miserably. I think this is one of the things worth studying—vegetable poisoning as distinct from red-water. In these particular cases I made no examination of the blood. These were cases such as I believe Mr. Doyle has previously treated successfully as vegetable poisoning in that neighbourhood.

There was one point as regards broken wind which nobody seemed to pay any particular attention to—the mechanical action of shot. We were taught in our young days to diagnose broken wind as a want of synchronising of the different respiratory parts—you know the double heave; and we thought, whether rightly or wrongly, that by loading the stomach with shot we would just restore the balance—and it succeeds. Whenever you suspect that the thing has been done give the animal a good drink of water and the dope has lost its power.

The CHAIRMAN: Before asking Mr. Magee to reply I must say how much I appreciated his paper. I was very interested in the cases he described. I would have liked a little more information about the case of amputation. He said that after applying two ligatures he seared the stump with a hot iron. I wonder was there much haemorrhage; and if not, why did he use the actual cautery? Was it for the purpose of destroying the stump and making it come away more easily, or to sterilise it? The sow being in a collapsed condition and apparently at the point of death, did he give it any restorative or stimulant? What after treatment did he adopt? Did he order the vagina to be washed out periodically; or prescribe any medicine for the sow? I would like to know if he had many cases of this kind, and what was his success with other cases. I remember reading an account by an Italian veterinarian of the remarkable successes he had with this operation in various animals. It would make one think that really he was not telling the whole truth. For example, he amputated the uterus in 86 cows with 77 recoveries, in 8 mares with 6 recoveries, in 27 sows with 22 recoveries, in 9 bitches with 9 recoveries, in 4 goats with 4 recoveries, in 3 sheep with 2 recoveries, and in 3 cats with 3 recoveries. I have not had an operation of this kind myself, but I have had a few cases of hysterectomy through the abdominal wall with varied success. The most interesting case I had was that of a 14 yrs. old Chow bitch afflicted with

hysterocele. On opening the hernial sac I found that it contained portion of both uterine horns which were distended at intervals by swellings varying in size from a walnut to a hen's egg, due to accumulations of pus. I proceeded to amputate the organ, and tried in vain to draw out the remaining parts of the cornua through the hernial opening, the swellings therein prevented their exit. I was obliged to incise the hernial ring to enlarge it and even then I had difficulty in getting them out. On bringing the body of the uterus into view I applied ligatures in the usual way and removed the organ. I swabbed the stump with a solution of potassium permanganate, and finished the operation as usual, ligating the hernial sac and suturing the hernial ring and the skin. The wound appeared unhealthy for 2 or 3 days, then commenced to granulate nicely, and the patient made a good recovery. I consider the case worth mentioning on account of the combination of the two conditions—hysterocele and pyometra, and the complete recovery of the patient although 14 yrs. old.

I met with a remarkable case of intussusception in a mare recently. A valuable 5 years old draught mare had difficulty in foaling and a layman, after prolonged interference, delivered the foal. The mare strained violently afterwards and caused about five feet of invaginated bowel to be prolapsed through the anus.

I saw the mare about 16 hours after the accident with the prolapsed mass almost touching the ground and commencing to gangrene. I considered the case hopeless, but decided, in conjunction with another veterinary surgeon, to amputate the prolapse after cleaning it and drawing upon it to expose a healthy part.

I brought the peritoneal surfaces of the invaginating and invaginated parts into apposition by Lembert sutures and cut off the bowel behind the line of sutures. The mare was already suffering from the effects of infection of the peritoneum, and died the following day.

The case of obstruction in the foal and the use of the forceps in connection with it reminded me that I found Mr. Kenny's bitch forceps very good in cases of obstruction of the bowel in the dog, where you can barely reach it with the finger, one jaw of the instrument serving as a blunt curette to push between the bowel and the impacted mass to break down the latter.

I have nothing to add to what has been said about the cases of the two thoroughbreds.

I think I have never been at a meeting at which there was a better discussion. It was a really good practical instructive discussion. We are indebted to Mr. Magee for having provided for it by his excellent paper and very interesting specimens.

#### REPLY.

Mr. MAGEE: I am very glad that you have considered my short paper interesting. Regarding the remarks of Capt. Winter as to the length of time for which a broken winded horse can be set, I was inclined to think that the effects of the dope would only last 24 hours. My father-in-law, who was a horse dealer, told me that a horse he bought at a fair remained set for three days after bringing him home, and then broke.

What Capt. Winter says as to the use of a tallow candle and injections of oil in the treatment of constipation in newly born foals may succeed in some cases, but with those I refer to I don't believe that any injections or suppositories would have the effect of dissolving the hard masses of meconium, the consistency of which I can only compare to hard putty, or, in some cases, almost concrete.

Before I adopted this method I lost a foal affected in the way I have described. I administered oil by the mouth and repeated injections of oil and warm soap solution, and tried to break up the mass with a spoon, but it was useless. A great advantage of the forceps is

that once you grasp the obstruction it cannot slip away, as it bulges somewhat through the perforated jaws of the forceps. When gentle traction is applied a piece of meconium several inches in length will sometimes come away. The outside edges of the jaws being convex seems to prevent the bowel being injured.

In referring to the cases of the two thoroughbreds, Capt. Winter said that a good many of these occurred in America. I know myself from reading American veterinary magazines that they are very keen on the subject of forage poisoning, and I also think we have more of it over here than we realise. However, the reason I don't think that this was a case of forage poisoning is that they only received the oats and hay when they came in each morning. One got bad a few hours after coming in, and the other took ill in the paddock. That, I think, would point to their having obtained the poison, or whatever it was, sometime during the night. The oats and hay were above suspicion. As regards Mr. Doyle's suggestion of sorrel poisoning, I don't think it affords an explanation, because there were also cattle in the paddock, and they would have become affected just as likely as the horses. They were there from June to October.

In cases of intussusception I think that where jaundice is caused by it the telescoping is likely to be in the small bowel, because if it were far back in some of the large bowels the bile could pass along for a considerable distance, performing its functions, and would not be so likely to be absorbed into the system and cause the yellow discolouration of the skin and membranes.

Mr. Healy spoke of a whistler being set. I did not know it was possible to temporarily prevent the noise made by a whistler or a roarer. I remember a farmer, who was evidently not afflicted with too much conscience, once telling me that he succeeded in getting a whistler passed by giving him a pint of glycerine some hours before he was examined. This may be so, for glycerine is a wonderful thing in many ways; but I can't understand the mechanism of a dose of shot and butter or fat disguising the symptoms of broken wind so that it will last for 24 hours or more. Professor Mason said the test for that is to give water to the animal. But I gave this mare water and hay which she took, but it had no effect. So evidently shot was not the dope in my case.

Since I wrote the paper, a horse dealer, who has the reputation of knowing most of the tricks of his trade, and who apparently has his own idea about "doing his bit," told me that he passed a broken winded horse into the army by giving it two wine-glass-fuls of paraffin oil in a pint of linseed oil.

Mr. Wilkinson referred to the difference between the symptoms of broken wind and asthma. Personally I believe I have only met two cases of genuine asthma, both of which recovered in a few weeks without treatment.

In asthma the respirations have a typical wheezy, asthmatic sound which is not present in broken wind, although the respiratory movements are often very much alike. In some pronounced cases of broken wind you have the characteristic double movement and in others you have not—you have only the heaving. I don't know what the explanation is. That all cases are not due to the same cause I am confident. I have completely cured some with vergotinine, while on others it hadn't the slightest effect.

Mr. Lambert explained a point about the terrier swallowing the inside of the golf ball on which I was not clear. I thought he swallowed the ball and that the cover was digested in his stomach. [Mr. Lambert: He only swallowed the core.] Mr. Lambert asked me did I use arecoline in cases of choking. I did so once with success in a horse where the stoppage was between the lungs. I also gave a little linseed oil. I think

arecoline is a good thing in such cases. [The Chairman: Some say eserine is good.] Mr. Magee: Professor Craig is inclined to doubt, and, perhaps, rightly so, that the jaundice was caused by the intussusception. I think, however, when you make a post-mortem and find invagination of the small bowel and no other pathological condition present, except jaundice, that is a natural conclusion to come to that the bile was dammed back by the telescoping of the bowel and not *vice versa*, as he suggests.

Both Prof. Craig and Mr. Norris spoke of the likelihood of asthma being mistaken for broken wind. There is no doubt that this may easily occur. I think I know the case Mr. Cushman referred to. It happened in County Meath. My own opinion as to the dope most often given to broken winded horses by tinkers, etc., is that it is one of the drugs containing atropine, however they obtain it. [Mr. Knight: Antimony is the stuff they give them.]

Mr. Norris's suggestion that the cases of the two thoroughbreds might be the result of the slow accumulation of some vegetable poison in their systems till it became toxic is not, to my mind, satisfactory. If it were the case it is improbable that the two horses would have become affected within a few hours of one another. [Mr. Norris: Oh, yes, they would. In the experiments the animals went down about the same time. It was three weeks before any symptom was shown and then one of the animals suddenly showed acute symptoms and died, followed, the next day, by another one. The test in one case was ragwort which was supposed to have no poisonous effect whatever. It has been shown that the poison accumulates in the system until it has a poisonous effect.] Mr. Cushman mentioned how unsatisfactory post-mortems often are, and I am sure we have all had that experience. But I think I can say that in almost all fatal cases of genuine colic which I have met; where the animals showed manifestations of abdominal trouble and did not become paralysed, I have been able to find a satisfactory explanation on post mortem. I have, however, met several peculiar cases where the pain was associated with paralysis from the start, and to which a P.M. examination gave no clue. In my experience fatal colic attacks were due to twist, rupture, intussusception, enteritis, peritonitis and thrombosis.

Prof. Mason suggested that the bullock that passed the blue water might possibly have received methylene blue in the form of medicine. I am certain he did not.

In reply to Prof. O'Connor, my reason for searing the stump of the neck of the sow's uterus was to sterilise it, and to prevent possible infection afterwards. I did not give a stimulant, although I think it would have been advisable. No after treatment was advised—on the principle that, in such cases, and with people who often don't carry out instructions, it is best to leave well-enough alone. I cannot say what ultimately happens to the stump behind the ligature, but I am inclined to think that it eventually sloughs off. The cases reported by our Italian friend, Lanzilotti are certainly wonderful. His successes, however, appear to me to be, in vulgar parlance, "pretty thick." A Scotchman would say "I hae me doots." I have had only two successes, although I have performed the operation on six occasions. I said there are pitfalls to be avoided. If the animal is far gone it won't stand the shock. We must also be very careful in tying the ligature, and to leave a sufficiently long stump behind it: if the ligature slips off there will be fatal haemorrhage. One should also make certain before starting to operate that there is no hernia of the intestine into the uterus. I had such a case and it was certainly an "eye opener".

In conclusion I have only to express my thanks to you for your kind remarks, and for the interesting way you discussed my short paper.

The CHAIRMAN: I think we may congratulate ourselves on the very successful meeting we have had.

Mr. NORRIS proposed a hearty vote of thanks to the Essayist and said that he always thoroughly enjoyed a paper from Mr. Magee because it dealt with matter of practical and scientific interest which led to an excellent discussion.

Mr. CUSHNAHAN said he had much pleasure in seconding the motion.

Mr. MAGEE in responding said he was very glad that his paper was so much appreciated and, judging from what Mr. Norris had said, he considered he was justified in feeling proud of his little effort to provide material for discussion at their meetings. He would be very glad to do so again but before that he hoped others would come forward with papers. He would suggest that their President present one soon, on a surgical subject, for he had a high opinion of Prof. O'Connor's skill as a surgeon, and had availed of it in connection with operations with which he had not been familiar; but having seen Prof. O'Connor operate he had no hesitation in tackling them himself afterwards.

Mr. HEALEY proposed and Capt. Winter seconded a vote of thanks to the Chairman.

The CHAIRMAN acknowledged, and said he was grateful to Mr. Magee for his kind reference to him.

## YORKSHIRE

### VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A.—NORTHERN BRANCH.]

The Annual Meeting was held at the Hotel Metropole, Leeds, on Friday, February 21, at 3.30 p.m.

The chair was taken by the President Mr. S. E. Sampson, M.R.C.V.S., Sheffield, and the following were present:—Messrs. MacCarmick, Crawford, Captain Somers, Lieut.-Col. Bowes, Lieut.-Col. Mason, Mr. Barber, and S. Wharam, Leeds; Major Ellison, Harrogate; Major Pawlett, York; Major Geo. Whitehead, Batley, P. Deighton, Selby; J. McKinna, Huddersfield; H. Pollard, Wakefield; and H. M. Holland, Keighley.

*Minutes.* Mr. Wharam read the minutes of the last meeting, the Secretary being unfortunately absent from illness. Moved by Mr. McKinna that the same be confirmed. [Carried.]

*Apologies: Correspondence.* Apologies for absence from Mr. Locke, Dr. Bradley, and Mr. Clarkson.

*Resignation.* Mr. Tom C. Fletcher, of Sheffield, desired to resign his membership, owing to an accident which prevented him from getting about as formerly. It was unanimously decided to ask Mr. Fletcher to reconsider his resignation, as not only he but his father was an enthusiastic member of the Association, and old associations should not be severed.

The PRESIDENT rose and said he desired to record the loss to the Association by the deaths of two members, Capt. Thexton, R.A.V.C., of Pontefract, who died abroad on active service; and Mr. H. Snarry. He proposed that a letter of condolence be sent to the nearest relatives. Carried *sub silentio*, the members upstanding.

*Balance Sheet.* The Treasurer presented the balance sheet, showing a credit balance of cash at bank £28 8 4 and a reserve of £50 war bonds. Proposed by Mr. H. Pollard, seconded by Mr. S. Wharam, that the balance sheet be received and adopted. [Carried.]

Mr. MCKINNA said he thought the insurance of the bookcase and its contents too low, and proposed that it be increased from £50 to £150. Seconded by Mr. Philip Deighton. [Carried.]

The TREASURER reported on arrears of subscriptions. Resolved to refer matter to Council of the Association.

*Forthcoming Election of Council R.C.V.S.* A note was read from Mr. G. H. Locke, of Manchester, saying

he had been nominated for election to Council, and desired the support of the Societies.

The PRESIDENT said the Council of the Yorkshire V. M.A. had nominated as their official candidate Mr. S. Wharam, which action was confirmed by the meeting.

Mr. WHITEHEAD proposed they should join with other Societies, as in former years, to secure the return of their official candidate. Mr. Crawford seconded, and was supported by Mr. P. Deighton, and Mr. McKinna. [Carried.]

*Election of Officers.* Mr. McKINNA proposed that the present officers be re-elected *en bloc*. He said they had not had their usual complement of meetings, and they hoped now to return to normal conditions. Seconded by Lieut.-Col. Bowes, and supported by Capt. Somers. [Carried.]

Mr. S. E. SAMPSON the retiring President returned thanks for his re-election. He had been persuaded by the Council to accept office again, and hoped their Secretary would have better health. There was a great amount of work to do, and he should like the meetings more regularly as now members were returning to civil life they could attend better and all help with reconstruction.

The PRESIDENT introduced the question of insurance fees and read a letter, and asked for further discussion.

#### NORTH MIDLAND VETERINARY ASSOCIATION.

Dear Sir,—At a meeting of the Council of this Association held at Sheffield on February 18th, the question of insurance fees came up for further discussion, and I was instructed to inform you that the Council are recommending members of the Association to charge the following fees for inspection of animals for insurance companies.

A minimum of 5/- each animal up to £50 insured value, with a rise of 1/- per £10 up to £200. 6d. a mile one way extra to be charged if the distance travelled is over 3 miles.

I was also instructed to ask all veterinary surgeons residing within the radius of the Association to give a written guarantee that they would not examine animals for insurance companies for fees less than the above. It is only by combination that the fees paid by insurance companies can be raised, and seeing that animals are now greatly increased in value, and that consequently the insurance companies are receiving greatly increased premiums, the present seems the time to get such an increase.

I shall be glad therefore if you will sign the guarantee at the foot of this letter and return it to me at your early convenience. If I do not receive such guarantee I shall take it that you are not in agreement with the proposed scale of figures.—Yours faithfully,

J. S. LLOYD, F.R.C.V.S., Hon. Secretary.  
Town Hall, Sheffield, February 20th.

#### Guarantee.

I hereby agree to accept the above scale of fees for veterinary inspection for insurance companies, and undertake not to carry out any veterinary inspection for insurance companies at fees less than those mentioned in the scale.

Signature. Address. Date.

Mr. HOLLAND said the Insurance Companies will pay more if requested. He had obtained increased fees in many instances in that way.

Capt. SOMERS said it had been a scandal for years, and the fees should be raised, not only for examinations in insurance but in contracts. Some of the Railway Companies paid a ridiculously low contract price; everyone knew the extra cost of every thing; £1 was only worth about 9/-. The blacksmiths had raised their prices. All the companies were well able to pay more.

Mr. McKINNA: The charge per mile is not enough. I think 1/3 per mile one way, after the first two miles, and a minimum of 5/- would be reasonable.

Mr. BARBER: The minimum that I try to get is 7/6, with mileage in addition.

Mr. CRAWFORD thought 5/- minimum and extra for mileage, it could not be done under 9d. a mile.

Mr. WHARAM proposed the Association support the agitation for an increase in insurance fees paid to veterinary surgeons. Seconded by Mr. Deighton. [Carried.]

The PRESIDENT said the recommendations would be sent to the Association of Insurance Companies, London, which included all Tariff offices.

*Resolved*, on the suggestion of the President, to send a letter to the Secretary, hoping that he would soon be well again.

Mr. WHITEHEAD read a scale of fees recommended by a Veterinary Society. *Resolved* that the subject of veterinary fees and contracts be put on the agenda for next meeting; in the meantime the Council of Yorkshire V. M.A. to prepare a scale of fees for all classes of veterinary services, and present for discussion.

The PRESIDENT asked if there were any members wishful to report interesting cases.

Mr. POLLARD mentioned a case of gathered nail and open joint. After treatment had been proceeded with the discharge ceased, but lameness continued. The owner wrote Mr. Pollard to the effect that he had obtained a second opinion, but as the events were recent Mr. Pollard had not yet heard who the consultant was, but would report at the next meeting.

Mr. WHARAM recorded a case of simple fracture of the humerus. The animal, a 17 h.h. Shire mare, 5 yrs. old, bolted whilst the boy was throwing some manure off the cart, she went about 100 yards and fell over a low garden wall; was walked home, and was not very lame. The accident was on Feb. 13th; on Feb. 20th the mare was reported worse and the humerus was found to be fractured. There was no suspicion of a fracture when examined the day following the accident. The owner had exercised the mare, and said the lameness had improved. As the mare was slaughtered for the Belgians I am unable to produce the bone.

A vote of thanks to the President for his conduct in the chair concluded the meeting. The members present were entertained to tea by the Association.

#### THE DERBYSHIRE RESOLUTION.

Sir,—“Sceptic” has prescribed a useful affusion for application to the megacephalic assembly at Derby, in advising them to avoid suicide. How little can they know of their own value in the eyes of the show world—or indeed of the world of men and things, if they suppose that a business recognised as lawful, and with millions of capital behind it, can be suppressed by a fatuous attempt to upset agricultural exhibitions by abstention from the work of veterinary inspection.

If members of the profession had the instinct for combination so highly developed in miners, still they could be done without.

Disintegrating influences are at work, and no single act of our governing body has done so much to make strife and ill will, and create spies, snobs, and sneaks, as the passing of a rule forbidding advertising. By that self-denying ordinance we have thrown away the substance for the shadow. Where orders used to come in for draughts and drenches by dozens, and allowing good profit, we now dispose of nothing more than we prescribe for cases visited, because we have driven the “trade” into the hands of great firms with practically unlimited capital, and as a rule with a M.R.C.V.S. on the directorate. What rot it is to speak of quack medicines when our

grievance is that we are not the sellers of it ourselves. Who will tell us that he honestly believes that the veterinary medicines sold by reputable firms are not as well suited to owners needs as any we can dispense for stock purposes, and not specially for individual cases. If there is one such reader, what does he think of our leading lights in the Army, having to fall back on a proprietary dip after killing many animals with unsuitable dressings, and failing to deal with sarcoptic mange successfully until the said preparation was employed. So too with lice. None of our preparations will kill nits, and we had finally to adopt another proprietary preparation which does answer the purpose, and is safe for all animals. If a finance act puts a stop to building, it should be amended. If we have passed a bye-law inimical to our welfare, we should rescind it. The attitude of our Derby friends reminds me of a hen with one chick which I saw trying to drive a bull out of a paddock.

"FRA DIAVOLO."

#### A QUESTION OF PROCEDURE.

To the Editor of the "Veterinary Record."

Dear Sir,—At the meeting of the Council on January 10th last, the President ruled that when the vote was taken on the report of the Registration Committee, the names of the voters one way or the other were not to be recorded.

This means that members of the College are to be kept ignorant of how their representatives vote in important matters. Presumably the President was acting within his powers, but if he had any choice in the matter I cannot help thinking that he was ill advised.

Most of us would like to know how our representatives vote, in order to assure ourselves that our confidence has not been misplaced and to guide our decisions at future elections.—Yours faithfully,

Poona, India.  
Feb. 2, 1919.

G. K. WALKER, Lt. Col. I.C.V.D.

#### INSURANCE FEES.

I had the assistant manager of one of the large Insurance Companies staying with me a short time ago, and we were discussing the matter of veterinary fees. He stated that it was not the Companies' fault that the fees were so low, but our own fault, as he could produce a letter from a veterinary surgeon asking for their work at the present low fees; and that until veterinary surgeons combined so as to stop this writing for work at so low a fee we should never get better treatment, as the Companies were only willing to pay 10/-.

H. BIBBEY.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919 :—

	Mar. 18.
H. W. Brekke, Hull.	£1 1 0
J. A. Connell, Major, R.A.V.C.	1 1 0
H. H. Hide, Lower Edmonton,	1 1 0
T. Hodgins, Capt., R.A.V.C.	1 1 0
T. J. Kenny, Capt., R.A.V.C.	1 1 0
C. Pack, Lymington.	1 1 0
R. A. Philp, Brentwood.	1 1 0
J. Temple, Aberdare, Glam.	1 1 0
J. H. Wynne, Denbigh.	1 1 0
J. Stow Young, Capt., M.C., R.A.V.C.	1 1 0
Previously acknowledged	667 8 0
	£677 18 0

#### ANGLO-FRANCO-BELGIAN VETERINARY RELIEF FUND. 10 Red Lion Square, W.C. 1.

The following Donations are gratefully acknowledged :—

J. Aitken, Dalkeith	£1 1 0
E. P. Barry, Lt. Col. 2nd Life Guards	2 0 0
J. D. Bremmer, Valentia, Ireland	1 0 0
T. E. Burrage, Lt. Col. R.A.V.C.	1 1 0
G. A. Bushman, Islington	1 1 0
H. W. Caton, Mile End, E.	1 1 0
M. Clarkson, Satron, Richmond, Yorks	1 1 0
J. R. U. Dewar, Edinburgh	5 5 0
Jno. A. W. Dollar, London, W.	10 10 0
E. R. Edwards, Board of Agriculture	1 1 0
A. L. Farrant, Hove	1 1 0
W. J. Fletcher, Wrexham	1 1 0

#### ARMY VETERINARY SERVICE.

Buckingham Palace, Mar. 15.

His Majesty held an Investiture in the Ball Room of the Palace.

The following were severally introduced into the presence of His Majesty, when the King invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted :—

\* \* \* \*

#### THE DISTINGUISHED SERVICE ORDER.

Lieut.-Col. Victor Leckie : Major Reginald Mellard.  
War Office, Mar. 13.

The King has been pleased to confer the Territorial Decoration upon the following officers of the Territorial Force who have been duly recommended for the same under the terms of the Royal Warrant dated Aug. 17, 1908, as modified by the Royal Warrant dated Nov. 11, 1918 :—

\* \* \* \*

Maj.(actg. Lt.-Col.) E. M. Perry, F.R.C.V.S., Maj. R. L. Green, Maj. F. J. Taylor.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Mar. 15.

#### REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Maj. J. J. Griffith, D.S.O., retires on ret. pay (March 16), and is granted the rank of Lt.-Col.

Maj. J. J. Griffith, D.S.O., relinquishes the actg. rank of Lt.-Col. (March 2).

Temp. Capt. G. C. Harding relinquishes his commn. on account of ill-health contracted on active service (March 16), and retains the rank of Capt.

Mar. 17.  
The grant of the temp. rank of Lt.-Col. to Maj. A. J. Thompson, notified in *Gazette* Dec. 1, 1917, is ante-dated to Aug. 14, 1916.

Mar. 19.  
Capt. C. Tracy is placed on ret. list on account of ill-health caused by wounds (March 20).

TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

Mar. 13.  
Capt. F. W. Pawlett to be actg. Maj. whilst holding the appt. of D.A.D.V.S. (March 1).

#### The R.A.V.C. Comforts Fund.

Subscriptions and gifts to the above Fund will not be received after March 31st. The Committee wish to thank all who have so generously assisted in making the Fund a success: and to express the thanks of the N.C.O.s. and men of the Corps for the many comforts they have received.

E. A. BLENKINSOP, Hon. Sec.  
29/7, Bramham Gardens, S.W. 5.

#### OBITUARY.

JOSEPH PEARS, Penrith.

H. & A. S. 1860. Graduated Edin: 22nd Nov., 1879.

The death occurred at Wigton on Thursday, 13th March, of Mr. Joseph Pears, formerly of Penrith, one of the oldest and best-known veterinary surgeons in Cumberland. Deceased, who was in his 91st year, obtained his certificate in 1860, and commenced practice in the Penrith district. At the time of the dread cattle plague (Rinderpest), which ravaged the country in 1866, he was one of the chief veterinary inspectors for Cumberland and Westmorland; he also took a prominent part in helping to stamp out outbreaks of foot-and-mouth disease. He served a year as President of the Border Counties' Veterinary Medical Association, and in 1889 was appointed veterinary inspector for the Penrith Urban District. Some years ago he took into partnership his son-in-law, Mr. T. Bowlas, Penrith, and practically retired from active professional work in 1907. Mr. Pears celebrated his golden wedding in 1911, and his wife died in January last.

VOL. XXXI.

## BROKEN WIND.

Some useful discussion of this subject took place at the recently reported meeting of the V.M.A. of Ireland. Not a little information was gained; and the important truth that we have yet much to learn regarding broken wind itself, the methods of temporarily concealing its symptoms, and the still more imperfectly understood conditions which may occasionally be mistaken for it, was well brought out.

There has always been much mystery about the practice of "setting" or "stilling" broken winded horses. Probably there are still some clinicians who doubt its possibility, and perhaps a few who even deny it. Most, however, are now agreed that the thing can be done; but many are more or less vague as to the methods of doing it. We have now more assured scientific information on the subject than we once had; but there is still much to be learned.

Reitsch's experiments at Budapest have shown us one method of "setting" and given us some hints for its detection. We now know that the administration of leaves, roots, or seeds of plants containing atropine will effectively "still" broken-winded horses, reduce the frequency of respiration, and also abolish its double period and forced character. The affect appears after fifteen minutes and lasts a whole day, after which the dyspnea returns with increased severity. Other effects of this method are that the horse shows dilatation of the pupils (and sometimes visual disturbances also), a considerable increase of the pulse-rate, and, in the first hours after the administration of the drug, great dryness of the buccal mucous membrane. The mouth is usually rubbed with fat to mask the last symptom. These points are valuable for the detection of this particular method; but we do not know whether it is as common in the United Kingdom as on the Continent.

Numerous other agents are known or believed to be used for the same purpose. Shot, fat, laudanum, antimony, and aconite are examples; and another, the combination of paraffin and linseed oil, mentioned at the Irish meeting, is perhaps not so widely known. Some of these are probably more or less effective, and all may be; but it is doubtful whether any would be so easy to detect clinically as the atropine method. It is difficult to understand how some of them can produce whatever effects they have upon the condition; and the difficulty is increased by our lack of knowledge as to the pathology of the disease and the mechanism of the production of its symptoms. The commonly accepted view—an old one, regards the pathology as that of chronic pulmonary emphysema; but there is much evidence to make us doubt whether that explanation covers every case.

Probably most clinicians who have thought much upon the subject agree with the opinion expressed at the Irish meeting—that more than one pathological condition may cause the characteristic symptoms, and that these are commonly classed together as "broken wind." The question next arises whether all or any of the various "setting" methods are equally effective in all cases; for that they are so is by means a certainty. Almost every point connected with broken wind requires further and systematic investigation. Some of the work could only be properly carried out by pathologists; but a great deal, including the most important practical question of the effect of drugs upon the symptoms, could quite well be done by clinicians.

This subject suggests amusing reflections to those who remember the dogmatism of some practitioners of old days. As a rule, no case is easier of diagnosis than a well developed one of broken wind; and on that account many "practical men" have been able to persuade themselves that they know all about it. Yet, if we examine the extent of our present knowledge of this classic disease, we find that in reality there are few animal ailments which are at once so widely recognised and so little understood.

## Royal College of Veterinary Surgeons.

### EXAMINATION COMMITTEE.

A Special Meeting of the Examination Committee was held at 10, Red Lion Square, on Friday, March 21st, mainly for the purpose of dealing with applications from ex-service students and other matters.

The President reported the arrangement which had been arrived at with the Ministry of Labour with regard to the award of Maintenance and Training grants for Veterinary students. The Veterinary Profession has now been placed with other professions for which training grants can be made in all approved cases, without further reference as to the suitability of the Profession as a sphere of training.

Applications from ex-service Officers and men, both those whose course of study has been interrupted, and those who desire to commence the course, must be made out on Army Form Z 15, which can be obtained from the District Directorates of the Ministry of Labour, Appointments Department. A space marked "Training Required" is provided on the back of the form, and the applicant must state here his claim for financial assistance, in order to enable him to complete the course for the diploma of M.R.C.V.S. The form must then be sent to the District Directorate for the applicant's home district, from where it will be transmitted to the Grants Committee, Ministry of Labour, and it is hoped that in urgent cases a decision will be arrived at without much delay.

A full report of the meeting will be presented to the Council at the Quarterly Meeting in April.

## THE CENTRAL VETERINARY SOCIETY.

(NATIONAL V.M.A.—SOUTHERN BRANCH).

A meeting was held at 10, Red Lion Square, W.C., on Thursday, March 6th, Prof. Wooldridge in the chair.

The minutes of the last meeting having been confirmed, Mr. J. B. Buxton asked permission to make a statement.

On the motion of Mr. J. Willett seconded by Mr. Slocock, Mr. Buxton was allowed to make the following reference to the criticism of Sir John M'Fadyean which had appeared in the veterinary press with regard to his paper on "Coccidiosis in the Rabbit" read at the last meeting of the Society:—

Mr. President and Gentlemen—I should like, with your permission, to make a brief reference to a criticism which has appeared in the Veterinary Press of my communication to this society on "Coccidiosis in the Rabbit." The criticism was furnished by Sir John M'Fadyean, who took upon himself "a very uncongenial task," lest readers abroad should infer that "the study of coccidiosis in this country has been sadly neglected." It is not necessary or proper that I should inflict upon you my personal feelings with regard to the attitude which it has pleased Sir John to adopt, and I therefore confine myself to the mere mention and, if you wish, explanation of the various points which were raised. I owe this to you and also to myself.

When I compiled these few notes my intention was to summarise well known facts, facts which were presumably known to many of you who were present, and moreover facts which could be verified by reference to almost any text book on bacteriology.

This applies to the life history of the parasite, an exhaustive description of the various phases of which, however, I did not profess to enter into, and hence my suggestion that "some knowledge of the manner of reproduction was essential." This summarising and also possibly a certain looseness of expression of which I may have been guilty, appear to have laid me open to criticism. It was however practically an impossibility for any man possessing such a knowledge of the subject, as Sir John undoubtedly does, to have innocently misread those statements. The first impression which was created in my mind by Sir John's letter was that the views he held concerning this disease differed from those usually expressed and mentioned by me.

In reply to my letter however Sir John accused me of dishonesty in forming this opinion and again of a lack of knowledge of the subject. If there has been any dishonesty of action or thought—I submit that I certainly am not the guilty party. When I said that under certain conditions "the oocysts divide into two and then into four spherical bodies called sporoblasts," I may have been guilty of some looseness of expression. Had I said that there was a double nuclear division and four extrusions of the cell protoplasm which later became four spherical bodies called sporoblasts, I should perhaps not have laid myself open to such a virulent attack on that particular point.

Lest however, my original rendering should be considered a criminal misrepresentation of the actual facts I would refer you to Prof. Hutchins statement (Practical Bacteriology, Microbiology and Serum Therapy p. 762).

"If a number of oocysts be placed in a few drops of sterile water in a Koch's cell and kept at a temperature of 15-18 °C their contents will be seen in the course of two to three days to divide into two and later into four small spheres or sporoblasts."

With regard to my statement that "if a rabbit ingests such a cyst the wall becomes dissolved and the sporocysts are liberated, these in turn rupture and set free the sporozoites," and Sir John's criticism that "since the publication of Metzner's observations it has been known

that the wall of the oocysts does not become dissolved, that the sporocysts do not burst, and that the liberation of the sporozoites takes place without either of these things happening." Since Sir John has definitely stated that his criticism is based upon accepted facts it is unnecessary for me to mention differences of opinion which are held to-day by protozoologists regarding Metzner's observations, and I will therefore confine myself to the statements made in existing text books, and on this ground I contend that Sir John's criticism is the merest quibble.

Sir John has undoubtedly observed this phenomenon and he knows that as a result of the action of the duodenal juice, or even of commercial preparations of trypsin, upon the ripe cysts the sporozoites break and wriggle through the membrane covering the somewhat conical end of the sporocysts and leave the oocyst through the membrane at the flattened pole which has presumably been prepared by the action of the duodenal juice.

The method of expressing this phenomenon varies but little. Hutyrá u. Marek (Spizuelle Pathologie und Therapie der Haustiere page 716) state that "After the ingestion of the oocysts the outer case is dissolved (Aufgelöst) by the digestive juices more particularly the pancreatic juice."

Hutchens says (p. 762) "the capsule is digested and the sporocysts are set free." Buchanan (Veterinary Bacteriology) describes the formation of the sporozoites and their "liberation by a rupture of the cyst." It appears to me therefore that it is quite unnecessary for Sir John to have laboured this point. Sir John cannot be reproached for his adverse criticism of my drawing, since my statement that it was a rough representation of the life cycle of a coccidium was not published.

Sir John said further—"Mr. Buxton evidently does not know that macrogametes do not possess a micropyle, the thing so named being only seen in the oocyst." This is a most unwarrantable assumption. It is strange in view of this statement that Prof. Hutchens (p. 763) describing the structure of the macrogametes says "the granulations pass to the periphery, fuse and form an enveloping membrane, pierced at one end by an orifice, the micropyle." I am perfectly well aware that the thin portion of the membrane covering the flattened pole of the oocyst is called a micropyle and I am also aware that a similar spot on the wall of the sporocyst receives the same name although Sir John fails to mention this fact and indeed says "the thing so named (the micropyle) being only seen in the oocyst." If he doubts my statement I would refer him to Kolle in Wassermann (Handbuch der Pathogenen Mikro-organismen Bd 7 p. 716.)

Sir John challenges the statement that "a single male element penetrates the female cell at the micropyle, which then closes." I stated what I believe to be an accepted fact. I have not observed this fertilisation process myself, probably Sir John has been more fortunate.

The following is a translation from Hutyrá u. Marek (page 517.) "After the numerous microgametes become free they penetrate (eindringen) the macrogametes and fertilise them" and the following translation is from Kolle and Wassermann (p. 715). "A microgamete enters a macrogamete as in the case of E. Schubergi and the nuclei coalesce, while the penetration of the other microgametes is prevented by the excretion of a slimy substance," (page 713) "the microgametes swarm round macrogamete and one of them enters a protuberance for its reception after which a membrane forms upon the surface." Hutchens states (p. 764) "the mature macrogamete attracts the microgamete by chemiotactic influences, a single microgamete penetrates the female cell at the micropyle and as soon as it has passed into the macrogamete the micropyle closes behind it."

Further comment is unnecessary. Sir John contends that my description of the lesions is "equally inaccurate."

He asserts that "Abscesses are never formed in the liver in cases of coccidiosis in the rabbit." Such a quibble is unworthy of Sir John. These areas are commonly referred to clinically as abscesses, although they might more properly be described as abscess-like cysts.

Lastly, Sir John states that "the bile ducts do not become more branched and the connective tissue does not become hypertrophied, nor does it produce either venous congestion or atrophy."

I am still of the opinion that these changes may occur and in support of my contention I may quote Ostertag (*Hand-book of Meat Inspection* (p. 522.) "Later, a marked hyperplasia of the epithelia and a papillary proliferation of the bile ducts arise, so that these structures do not represent simple canals, but much-branched cavities." Jordan, in his *General Bacteriology* (p. 461) says "in these animals (i.e. rabbits) it evokes cirrhotic changes and other chronic inflammatory processes." Again, according to Wasielewski, quoted by Kolle and Wassermann, the liver becomes enlarged up to one-sixth of the body weight, instead of one-twentieth which is the average. Hutchens states (p. 760) "The biliary canals are dilated and the connective tissue hypertrophied, compressing the blood vessels and leading to atrophy of the liver substance." Many pathologists of repute appear therefore to be of the opinion that such changes may occur.

Gentlemen, that is all I have to say. I leave you to form your own opinion as to whether I have misled you, have been dishonest, or have shown a lack of knowledge of the subject—of all of which actions I have been accused—or whether I have been wronged. It seems to me to be regrettable that Sir John should have considered it necessary to employ a howitzer for the purpose of wounding a sparrow.

**Fellows Present.** The following Fellows signed the attendance book, Messrs G. P. Male, H. D. Jones, H. King, J. B. Buxton, H. J. Parkin, J. W. McIntosh, J. Willett, F. W. Willett, S. H. Slocock, W. N. Thompson, G. Upton, W. Perryman, Prof. J. Macqueen, Capt. J. F. Macdonald, R.A.V.C., and Capt. J. T. Angwin, R.A.V.C. Visitors, Dr. R. T. Leiper, and Capt. Higgins, R.A.V.C.

**Correspondence.** Letters were received from Messrs W. S. King, F. G. Samson, T. S. Price and N. Almond, regretting their inability to be present.

**Nominations.** The following gentlemen were nominated and will come up for election at the next meeting, Mr. Herbert Cyril Price King and Capt. Higgins R.A.V.C.

#### MORBID SPECIMENS.

DR. LEIPER, who attended the meeting at the President's invitation, produced specimens which he said he thought would be interesting to the members, particularly since the last discussion had concerned some of the diseases of the rabbit. He had noticed that in the discussion on Mr. Buxton's paper at the last meeting one of the speakers had referred to a condition in the rabbit which was apparently not due to coccidiosis but which might be of bacterial origin. During the last year there had been a great deal of public interest in the rabbit, and there had been a great mortality among rabbits. During the summer a large number of rabbits especially young ones, had been sent to him suffering from diseases of the liver which were supposed to be due to "globe" worms. He had found that a great number of these young rabbits had died of coccidiosis, but towards the end of September another condition began to appear. In older rabbits which were supposed to have died of coccidiosis, he could not find lesions of that disease. The small intestine was intensely inflamed and congested—

so markedly so that at first he had written to one or two correspondents and had said that he did not know the cause of death. There were no worms and there were no coccidia, and he feared that perhaps the matter was due to bad feeding; and he had directed the people to consult local veterinary experts on the subject. He afterwards found that that intense inflammation of the intestine was in many cases associated with an extraordinary "pepper-and-salt" appearance in the liver and also in the spleen, that the lungs were sometimes consolidated, and that it was really a septicæmia, and the specimens when fresh showed the little abscesses and necrotic areas very plainly. This septicæmia of rabbits had practically displaced the coccidia as a rabbit disease since the beginning of the winter. The spleen was extraordinarily enlarged. In some cases the small intestine, instead of being congested, was actually necrotic and of a wash-leather colour. The disease also attacked old rabbits. Quite large healthy rabbits succumbed in a few days. He had received specimens from all parts of the country. The following symptoms had been described by a lady correspondent, who was a very good and accurate observer, and who took a great interest in bacteriological work. During the summer she had reared a lot of rabbits for distribution, and had had big losses with coccidiosis; latterly she had noticed that the symptoms were not the same in all cases and had asked him to look into the matter. She wrote "The symptoms are the same in each case—first an attack of violent diarrhoea, which goes off in a day or two, followed at varying intervals by loss of appetite, extreme dullness of appearance and behaviour. The victims of coccidiosis, on the other hand, have excellent appetites up to the last, and generally die very suddenly, the only outward previous symptoms being more or less wasting, and in the case of youngsters retarded growth." Professor Hewlett had kindly examined the preparations, and had reported that the lesions were due to "one of the rabbit septicæmias." It was very similar to plague but there were some cultural differences.

The specimens exhibited by Dr. Leiper consisted of portions of liver, spleen, and intestines of an affected rabbit, and also microscopic sections of the lesions.

The PRESIDENT remarked that he did not remember having ever met with the condition, although he had seen quite a lot of diseased rabbits during the past year. He had had, however, very few submitted to him during the winter; he did not recall having had one in the past three months. He thought Mr. Thompson had been responsible for bringing the matter forward. He thanked Dr. Leiper for having exhibited the specimens.

MR. THOMPSON said the cases which he had referred to were those which had occurred in caviae. In that instance, he could not find anything on post-mortem but enteritis, and he had since come to the conclusion that that had probably been due from bedding them on sawdust with cresote, because all those cases had arisen the day after they had been re-bedded with fresh sawdust, or rather, with sawdust taken from wood which had been impregnated with cresote. The other organs were perfectly healthy, and the caviae showed no evidence at all of illness until 3 hours before they were dead. The deaths occurred at different times, and there seemed to be no connection between the three occurrences, and there had been only one affected on each occasion.

MR. MALE remarked that the lesions rather resembled those of bacterial necrosis which affected a very large number of animals.

DR. LEIPER said he personally could not pretend to give an expert view about the matter. If any fellow of the Society was interested in the matter he would be glad to hand over the material.

## THE SITUATION OF VETERINARY POLITICS.

By Mr. J. W. McINTOSH, M.R.C.V.S., F.R.S.E.

Mr. McIntosh said that having yielded to the philosophical persuasion of the Secretary, he found himself in the rather perilous position of opening the discussion on "the situation of veterinary politics." There could be no question as to the importance of the political aspect of the veterinary profession. The war happily was ended, and although it had brought much material and mental suffering, it had aroused the world into a state of national activity. It had opened up fresh avenues of fresh thought and action, and it behoved the veterinary profession and all organisations to see that they were in the van of progress. He would endeavour to put before the Society as far as time allowed a few points which, in his opinion, retarded progress and efficiency in a scientific sense and also those which raised or depressed the profession in popular esteem. Those of the members who had seen a little, thought a little, and felt more, must have observed the absence, in this country at any rate, of any tangible reward for purely scientific merit and scientific work. There was no external inducement to real exertion. What was the reason? He would ask the members for the moment to lose sight of minor points, amiable weaknesses and individual peculiarities, and ask themselves the question, whence had they come and whither were they going? Did they as a body occupy that position in the scientific and social world which they ought to occupy, and if not, why not? Were they content to run along on the old lines, and adopt a "wait and see" policy? Surely not.

He thought the first and perhaps the most important point was their position from the educational standpoint. Was the public aware that veterinary education in this country was almost entirely a matter of private enterprise, and did it fully realise the consequent insecurity of its foundation? Practically every department of education had been made matters of national concern, whilst the veterinary profession, which played such an important part in maintaining the life and wealth of the nation, was almost in a state of bankruptcy. Surely the profession had established a claim on the public purse. Unless the veterinary colleges were properly subsidised there was a probability of a breakdown in the whole present scheme of teaching. The position was serious, and if something is not done to foster the progress of veterinary education and veterinary research, the profession is bound to suffer, and as a result the country.

The next point was the profession's position so far as Government recognition and employment were concerned. Was the profession to remain as a graded division of agriculture? At present it found itself subservient to laymen and others who enjoyed privileges which undoubtedly the veterinary profession was entitled to. Were they to submit to the dictum of other departments, lay or expert? No other man, professional or lay, could possibly take the place of the trained expert in veterinary matters, and the profession and the public should see to it that he did not. It might be claimed that the duties of an inspector under the Contagious Diseases (Animals) Acts were inseparable from those of agriculture. But were they? Who said so? Not the profession, he thought. The only duties they had in common were those of watching over the interests of the stock owners and the welfare of the public. Circumstances would arise where consultations might be necessary, but each would have his duties to attend to. For an agricultural expert or any other expert to control or supervise the work of veterinary surgeons was injurious to the best interests of the country. The Chief Veterinary Officer ought to be the head of his department, and directly responsible for the work of his department to a Minister of the Crown.

A word about the New Ministry of Health Bill. There was little doubt that if properly constituted and honestly administered it ought to be productive of the greatest good. Were the profession sufficiently alert and watchful with regard to their interests in that direction? It had to be noted that the sister profession was carefully watching the progress of that Bill, but he was unaware of any action on the part of the veterinary profession. It was possible that the Council might be doing something in the matter. If so it was a pity that more publicity was not given to their deliberations and findings. If the profession was to negotiate effectively with regard to State recognition and employment they must organise on a solid and democratic basis, and if they were to enforce their rights and independence they must take no subservient position. They were quite entitled to enter into a compact for that purpose and to counsel all members of the profession to join together and withhold their services—if there was no other way of obtaining redress and of drawing public attention to their grievances: in other words, they must strike.

Another point which was exercising the minds of many was the question of part-time inspectors. The present system of appointing certain men for certain districts was, in his opinion, most unfair. It was not economic, and it was not calculated to bring about the best results. Unless it was clearly shown that a man was incompetent, every veterinary surgeon ought to be in a position to carry out the work connected with his own clients. He saw no reason why that man should not be in the same position as a medical man. Surely the profession did not consist of such a degraded lot that only a man here and there could be found capable of carrying out work of this kind. It was distinctly unfair that a country practitioner should have a neighbouring practitioner come to his clients to carry out the provisions of the Order. It gave that neighbouring practitioner an air of superiority in the eyes of the public—a sort of stamp of approval, as it were, by the local authority of the district. He was in favour, therefore, of doing away entirely with the part-time inspector, and appointing whole-time veterinary officers.

Might he venture to criticise for a moment the constitution and policy of the Council. He was sure everybody appreciated very highly the efforts of the Council. They did their best according to their lights, if their best was not good enough the profession had perfect right to say so. He had had some experience of public life and he knew what a thankless task it was, but any man who served in a public capacity, or in a semi-public capacity, must be prepared for criticism. It is only right that he should be criticised; it was a healthy sign of the times, and it was productive of good. So long as criticism did not descend to personalities, it was perfectly fair and reasonable—in fact he thought that the man who had never been criticised had done nothing worth remembering. It appears to him that the Council as at present constituted, was not sufficiently democratic. It was not sufficiently representative of the general body of the profession. Its policy seemed too much taken up with examinations, etc., and too little taken up with the scientific status and welfare of the profession itself. He was inclined to agree with the expressed view that the veterinary schools were over-represented. That was partly due to the fact that there were too many schools, and to the present system of elections. He thought to remedy the matter and to rouse the interests of the general body of practitioners was to have district representation. Why was it two-thirds of the profession took no interest at all in the work of the Council; simply because the present system of electing representatives was neither satisfactory nor equitable, and the majority of the Council were unknown to the profession. Some years ago he allowed his name to go forward as a candidate for Council honours. He had been generously

referred to (at that time) as a man unknown outside his own parish. Well, he contended that the man who was honourably known in his own parish and who had the respect and confidence of those around him was a man who was likely to carry with him into the Council chamber the interest of that district, and in that way the interest of the whole profession would be directly and democratically represented.

What was being done to watch the interests of their "Colonial Colleagues?" He was rather afraid very little. It was only right that such men should have a representative on the Council—not necessarily a colonial, but a representative elected by them, who would be able to submit their grievances, if any, and watch their interests. The conditions prevailing in the Colonies were not identical, therefore direct knowledge would be valuable.

He was not quite sure whether he agreed with the system of a man being elected to the Council for four years—he thought it too long.

Another point which he would like to mention was that of Fellows only being eligible as examiners. Surely no one seriously contended that a Fellow was any more qualified to act as an examiner than a member. It should be open to the whole profession to apply for examinerships, and appointments made on their merits.

Then there was a question very near to all of them in connection with demobilisation. It was beyond question that the home-coming of officers who had served several years in the Army would be fraught with many difficulties, both financial and professional. Those difficulties would vary according as to whether the man had been previously in practice or whether his civilian career lay before him. In the former case it would depend upon the kind of practice in which he had been engaged. No two cases could be quite alike, but the man who had a whole-time appointment awaiting his return, and the man whose interests had been safeguarded by an active partner needed little or no assistance. On the other hand, many a single-handed general practitioner might be looking forward with dread to beginning life again as the result of his prolonged absence. All know how elusive the goodwill of a private practice is. Even the utmost loyalty of their colleagues would not avail to keep together a man's *clientele* during four or five years' absence. Everybody would sympathise with a man who had given up everything to risk his life for his country, and it behoved everybody in the profession, in every possible way, to help in re-establishing those men to rise again to at least their pre-war level. Some members were already attributing loss of practice to the negligence, or worse, of their colleagues who had remained at home. That might be true in a few cases, but he would refuse to believe it of the general body of practitioners. In conclusion he urged the members to keep together and whilst each one might have his bias or tendency of thought, all had a common interest in the profession and ought, no matter how little it might be—even moral support is helpful—to contribute their mite to the treasury of knowledge, and so far as it lay in their power help to advance the interests of the profession to which they belonged. There must be no spasmodic effort. A united front and persistent effort—with no turning back, is what is wanted. If our position has been unsatisfactory in the past, do not let us be deprived of the future and "If at first we don't succeed, try, try, and try again."

Mr. UPTON desired to know how it was possible to legislate for a profession which had no legal *locus standi*. He viewed the matter from the point of view of the general practitioner, who was entirely dependent on the charity of stock-owners (murmurs of dissent). Mr. McIntosh might say that the profession ought to do this, that, and the other, but they had no hold on their clients

or on the country. Were they justified in creating professional agitation when a quack could take their positions? At present the profession did not attract men of birth and education. He had had it thrown up against him that his position in life as a veterinary surgeon was not good enough. Parents and guardians who placed their children or wards into a profession expected to get a return for their expenditure in the matter. The Diploma of the Royal College was not a guarantee of a living to the general practitioner. The training of the colleges did not altogether fit a man to earn his living. The profession was in the condition in which it was 50 years ago. It might be run as a side-line to a forge, or a farm, or a publican's business, but for a man to depend on it for a living he had to run it with something else. Under such circumstances was it to be expected that men of birth and education would be attracted into the profession?

Mr. MALE said he heartily agreed with and endorsed most of Mr. McIntosh's speech; but Mr. McIntosh had only dealt with one side of the question of part-time inspectors. As a part-time inspector himself, he (the speaker) might be allowed to put the other side of the question. The general idea seemed to be that if an inspector went to another man's client, that client immediately put his arms round the inspector's neck and adopted him as his veterinary surgeon. That was not the case. The fact was exactly the opposite. He would take swine fever as an example. The inspector had to attend the pigs usually belonging to a small holder, and probably did not see the owner at all. The inspector had to put the owner under restrictions, kill his pigs, do all sorts of things which the man objected to, and he never wanted to see the inspector's face again. Then in cases of mange, the probability was that the local inspector would not be called in. The owner would prefer to employ another veterinary surgeon. He (the speaker) had experienced that if a man had a horse which had symptoms of mange he would employ someone else than the local inspector to examine it, in the hopes that he would not find it necessary to call it a case of mange, and be put under restrictions and stop the work of the horse. The local inspector was the last man to be called in.

With regard to the finances of the profession, he did think it was absolutely deplorable that they had got into the condition in which they were. Some time ago he had gone round to one of the colleges, a college which was well known all over the world, for its good work, and for the splendid men who had taught there, and he had found that the teachers worked under most depressing conditions. They were very poorly paid, the laboratories were in a wretched condition, the appliances were not half what were required, and they had not the examples wherewith to teach the students. That was in a country which boasted of being the finest agricultural country in the world. The financial position of the Royal College was equally bad, or worse, and was fast going towards bankruptcy. Could not something be done? He did not know whether it was the fault of the Council. He had the greatest respect for the Council. He believed they did what they could, but surely there must be some way out of it. The veterinary profession was a very small one, and could not depend on the fees of the students to keep the education of the students up to the proper standard. Therefore it must have State aid for its colleges. Whether it was the duty of the Council to see to that or not he did not know, or whether they were trying to do it he did not know. If it was not the duty of the Council, then it must devolve upon the members to educate the public and to educate agriculturists, to the interests of the profession. Agriculture had been promised help for research work, and he did hope they all would do their

best to obtain sufficient funds for the veterinary profession, so that its students could be educated properly, and its lecturers and scientists paid equitably so that advance could be made accordingly.

Prof. MACQUEEN said he was exceedingly disappointed with Mr. McIntosh's remarks. Mr. McIntosh had mentioned some five or six points which apparently he regarded as grievances, but he had not suggested a single remedy. He did not even give a concrete case to support his grievances. What suggestions did Mr. McIntosh make except generalities which any man in the street could utter without knowledge of the profession? What was the present undercurrent of unrest in the profession? Was it a veterinary variety of Bolshevism? He (Prof. Macqueen) should say from his observations during the last few months that the spiritual home of that variety of Bolshevism was in Reading, and that the first gas shell had been sent over by his friend Mr. John Willett in December last. Since then there had been a few further attempts made to stir up agitation about the welfare of the profession, but the indictment had never got beyond generalities. He had not heard or read since the agitation began of a single well supported complaint regarding the welfare of the profession. The veterinary profession no doubt had suffered, and was suffering, like every other calling, and it was bound to suffer, but the remedy lay with the individual. It was useless to appeal to the Council. The Council had no power to look after the welfare of the members of the profession. It looked after education, and the conduct of the profession, but it had no means of supplying brains and ability, perseverance and assiduity. That was altogether outside its province, and for members to indulge in innuendoes, insinuations and general complaints against the Council was a waste of time, and it was worse than that, it was most ungrateful after the period through which the profession and the Council in particular had passed. Instead of grumbling round a table, members would be better employed in promoting a testimonial to the present President of the Royal College of Veterinary Surgeons, Mr. Garnett. There had never been a better President, and no man in the profession had devoted himself so continuously and energetically to its interests.

Mr. MCINTOSH said there had been no personal attack made upon Mr. Garnett.

Prof. MACQUEEN said he did not say there was any personal attack. There was a general complaint about the constitution and policy of the Royal College of Veterinary Surgeons. He maintained there was no ground for complaining about the behaviour of the Council. The only remark of Mr. McIntosh's with which he agreed was in reference to district representation. There was no doubt that if the profession as a whole was dissatisfied with the present members of the Council, the proper method was to return men who would give them satisfaction. How was that to be obtained? If it could not be obtained under the present Charters or Regulations of the Royal College, there was no power to enforce district representation. But there would never be what might be called a popular Council until the electors were able to return District representatives.

Then a complaint had been made with regard to Government recognition and Government grants. Did not the Government grant something to the colleges at the present time? ("Very little.") Was not there something more than an ordinary grant given to the Dick College? Was not there a grant given to the Glasgow College? What about the Irish school, which was said to be under Civil Service regulations? Was not it entirely a Government institution. Was not that Government recognition? What was wanted was a little more of that recognition, but he failed to see how any alteration was going to be brought about by simply shouting at the Council. What was required was propaganda

work. The members of the profession must be stirred up. Something had been said about educating the public. That was a very old-fashioned wheeze. The profession might try to educate the public, but it must first of all induce its members to take an interest in itself. Mr. McIntosh had acknowledged that two-thirds of the profession took no sort of interest in its welfare, and how were they going to be altered in this respect except by propaganda work?

With regard to the point that only Fellows could be appointed examiners, he believed the main reason for that was not because of any supposed distinction in brain power, but because of a belief that it might induce members to become Fellows. It had been thought that by restricting the appointment of examiners to Fellows it might induce more men to take the degree. The origin of the Fellowship was brought about by financial anxiety and only partly by a desire for a higher diploma.

He saw no reason for any very extraordinary agitation regarding the welfare of the profession, and certainly he saw no ground for attributing its present state to the Council, or hoping for its improvement from any action on the part of that body, unless its powers were enlarged, and that involved a new Charter, which would cost money. The profession would not be able to get much done by the Royal College of Veterinary Surgeons in its straitened circumstances. There was however, another body which might have far more influence in the matter of monetary improvement, and that was the National Veterinary Association. But that Association apparently was not much better than any other association in connection with the profession. Its membership was too small. To the last day there would never be unanimity in the veterinary profession. It was a profession with its initial too near the end of the alphabet. It was too close to X Y Z, and it would always remain in a condition of uncertainty.

Mr. J. WILLETT said he had every respect for the members of the Council, but as a whole they kept the profession too much in the dark. It was the secrecy of the Council which had caused and was causing the unrest in the profession at the present time. They might be moving in regard to the Public Health Bill, and watching the profession's interests, but the ordinary members were quite in the dark about it. It was time to abolish that system. The members wanted to know was being done. The sister profession was going strongly ahead, and would probably be strong enough to carry what they wanted. The question was, was the veterinary profession strong enough to go to the Ministry of Public Health and demand to have a part in it? He would like to know what the Board of Agriculture had done for the veterinary profession. He ventured to say that the profession had done far more for the Board of Agriculture. He quite agreed with Mr. McIntosh that the time had come when there should be a veterinary officer of health for every county. He strongly maintained that the veterinary surgeon's place should be in the Public Health Department, and not under the Board of Agriculture. Providing that veterinary officers of the Board of Agriculture still remained, they should be directly responsible to the Minister of the Crown, and not subjected to lay control. He also fully agreed with the idea of district representation, and he would like to see the Charter altered so that district representation could be brought into effect. He also agreed that it should be open to members of the profession to be examiners. If it was such a high honour to become a Fellow, why were not some of the profession's most able and scientific men Fellows of the R.C.V.S.? The Principals of the majority of the colleges were not Fellows. Then the Council in view of the repatriation of men should form an Intelligence Department.

The PRESIDENT said that such a Department had been formed.

Mr. WILLETT said he knew there was a Register kept at the R.C.V.S. for exchange and purchase of practices, also as to vacancies for assistants, but he had more in his mind that Colonial appointments might be dealt with by an Intelligence Bureau where candidates might be informed as to prospects and cost of living. With regard to Mr. Upton's pessimistic remarks, he (the speaker) would reply that the status of the profession depended on each individual, and as a man made his bed so he must lie. If a man was worthy of respect in the professional capacity he would get it. The *locus standi* of the general practitioner was determined by the individual himself.

Mr. SLOCOCK said that he was one of those who saw a bright opening for the profession. During the time he had been connected with it the profession had gone ahead very considerably, and if it continued to go forward at the same rate of progress he did not think there would be anything to be disappointed about. The total earnings of the members of the profession in the year preceding the war would compare very favourably with any period during the existence of the profession. He believed the total individual earnings at the present time would show a great increase on any previous earnings, and he believed future amounts would exceed even the present earnings. There were many openings in the profession at the present time which did not exist a few years ago, and new ones would ever be created. The standing of the profession depended a great deal on the individual. The working of the profession by the Council could be carried out much more easily if the Council were in possession of funds. If the Bill which enabled the College to make each member pay a guinea went through, it would place the Council in funds, and create more interest in the profession, because each man who paid his guinea would want his guinea's worth, and would be in sympathy with the idea of elevating the profession. He would become an active member, whereas at present he had lapsed into a state of apathy. As an example of apathy he would take the record of votes. How many men voted for members of Council? Again, to take a more striking example, how many members troubled to come to the Annual Meeting to express views? That was the place in which a member could air his grievances and criticise the Council. Of course, the good work of the Council was seldom taken into account, but the work undone was always recorded and was often imaginary. On the point of district representation he was not sure whether that would make any improvement on the present constitution, and he was not sure either that teachers could be done without on the Council. Personally he regarded the presence of teacher's representatives on the Council as being a very big asset. The education of the student was a most important matter, and who was better able to speak and direct them than the teacher? He was very happy with the present state of things, and he was sure that if the Council were supported with more funds they would be able to do much better work.

[On the motion of Mr. J. Willett seconded by Mr. F. W. Willett the proceedings of the Society were prolonged beyond the usual hour.]

Capt. ANGWIN quite agreed with the statements which had been made with regard to proper representation. As showing the lack of interest which many members took in the profession he quoted the examples of the various local societies. Previous to the war, the ordinary country practitioner would not attend the meetings of those societies, but he thought the experiences of veterinary surgeons who had been in the army during the war would alter that state of affairs. During the war they had learned forbearance in dealing with one another, and

had become fast friends, and he thought it would be found that when peace was finally declared there would be a great resuscitation of the local societies. Men would be more inclined to meet and exchange views, and band themselves together, and help to get local representation from different parts of the country. That was a simple solution of the problem.

Capt. ANGWIN then drew a comparison between the present state of the British veterinary colleges and the American veterinary colleges, which was much to the detriment of the former, and concluded by saying that it was money that was required. Until the Council obtained proper finance it could do very little.

The PRESIDENT thanked Mr. McIntosh for introducing the discussion, but said he did not agree with several of Mr. McIntosh's points. In the first place Mr. McIntosh objected to the veterinary department being subject to the Board of Agriculture. He thought it would be realised, however, that most of the veterinarian's work concerned the health of animals, and that must be regarded as one branch of agriculture, and one of the most important branches. He therefore failed to see, taken as a whole, that the veterinary profession could work more beneficially in connection with any other department than the Board of Agriculture. Although Mr. McIntosh objected to an agriculturist controlling veterinary surgeons—an objection which most members of the profession had—he (the President) thought it should be agreed that if veterinary surgery was one branch of agriculture, an agriculturist might co-ordinate the work of the various branches of agriculture. He should not control or dictate to the veterinary surgeon, but it was quite reasonable that he should co-ordinate the veterinary surgeon's work along with other branches of agriculture. He, like Mr. McIntosh, had been wondering what the Council had been doing in connection with the new Public Health Bill and the Ministry of Public Health. He had hoped that Mr. Slocock would have given some information upon that. In connection with the public health matter, one point was that at the present time the body concerned with public health matters, namely the Local Government Board, had already a veterinary surgeon on its staff, and although one was not cognisant with the actual duties performed by that officer, it was to be presumed that when matters particularly relevant to the health of animals in their relation to public health came up, that officer would be consulted. When that Board was taken over by the Ministry of Public Health, presumably that officer would go along with it. He did not know, however, to what extent that officer was consulted on matters veterinary, and rather feared that his position was due mainly, if not solely, to the fact that he was also a medical man. One had to remember, after all, that the question of public health was principally a question for medical men, rather than for veterinary surgeons. The question of meat and meat inspection, however, was primarily one for veterinary surgeons, because they were the only body that were trained in the pathology of animals, and were thereby fitted for that work. But it was not for veterinary surgeons to say what food should be eaten by man. His (the President's) view of the matter was that it was for the veterinary surgeon or the trained meat inspector to diagnose the condition of the flesh, and then it was for the medical man to decide whether or not that flesh should be used for food of man. He was strongly of opinion that there should be a veterinary staff at the Ministry of Public Health for advisory purposes relative to meat inspection and diseases transmissible from animals to man.

He was in cordial agreement with Mr. McIntosh on the point of full-time inspectors. In his view local practitioners should not be in the invidious position of having to inspect animals belonging to their own clients,

and to impose restrictions in the treatment of various diseases. He plumped for adequately remunerated, full-time Veterinary Officers of Health.

With regard to the question of the composition of the Council of the R.C.V.S., Mr. McIntosh had referred to the representation of schools thereon, but he (the President) thought they were not represented as such. The members of the Council were elected by the profession as a whole, and there was not a single one of them elected by the schools. Consequently he (the President) maintained that teachers were not elected on the Council as school representatives.

He agreed with Mr. McIntosh's preference for district representation. That would get over the reproach which Mr. McIntosh had levelled against the representation of the schools; but he (the President) would ask if it was suggested that a representative or two should be permitted on behalf of the whole of the schools, would other teachers be disqualified from being representatives of districts? If they were not to be disqualified the probability was that there would be just the same number of teachers on the Council, and possibly more. He considered a very strong case could be made out for district representation. The Council of the National Veterinary Medical Association was elected on that basis, and he would venture to prophesy that before many years were over there would be a very great change in the work of the National Veterinary Association, which he hoped would reflect itself in the matter of progress on behalf of the profession. Mr. McIntosh had suggested that there should be an election every year. He (the President) presumed he meant that the whole Council should be elected in one year and for one year only. That would be a great mistake, because it would ruin altogether any continuity of policy. Mr. Willett had suggested that the Council kept the profession too much in the dark, but work done in Committee could not always be published, because very frequently the point which was being aimed at might not be attained under publicity. There had however been an example during the past year of cross-purposes between the Council and the Central Veterinary Medical Society *apropos* the creation of a veterinary tribunal in connection with veterinary officers. It was unknown to the society that the Council already had the matter in hand, and because the society pressed the matter forward it got into trouble with the Council. The President of the Council had deplored the action the society had taken, although it was an action intended entirely to support the provision of a veterinary tribunal, which was ultimately obtained by the Council. Mr. Slocock had defended the Council. He (Mr. Wooldridge) fully agreed that the Council, and particularly the President, had done an enormous amount of work during the past few years which it had not been able to publish. It might be that in the present period of reconstruction many alterations would have to take place. Now was the time to try to get those alterations made. Shouting or open discussion was one means of propaganda, and he thought that was one of the ways by which matters might be advanced. Mr. Slocock said he did not want any change, and was quite content with present methods, but that was not an attitude which he (the President) thought would commend itself to the bulk of the profession.

Mr. Slocock said he desired to do away with the apathy of the general body of the profession.

The President said that would be done away with immediately the Council showed its cards more to the profession. Mr. Slocock had also pointed out that members could attend the Annual Meeting and voice their points there, but he (the President) had been to some of those Annual Meetings, and if members had attempted to voice their complaints they had been promptly

snuffed out; they had been told the matter was not on the agenda.

Mr. Slocock pointed out that there was a Parliamentary Committee of the Council which dealt with all Bills that were brought forward. Every Bill was watched by experts on behalf of the Council, and every clause of a Bill which affected the profession was considered. The Bills did not go through without the knowledge of the Council. All the periodicals of the day would be required to record all the work done by the Committees of the Council. Anything affecting the conduct of the profession was taken up, and if any deputation was appointed the President was always at the head of it.

Mr. McIntosh, in reply, said the object he had in view in bringing forward the subject had been more than fulfilled. Mr. Upton had taken a very pessimistic view of the profession—he always did, but he (Mr. McIntosh) had not lost faith in it. He was really surprised to hear Mr. Upton suggest that the profession should be tacked on as a side-line to various other things. We are too much nibbled at now. With regard to part-time inspectors referred to by Mr. Male, he had said nothing against part-time inspectors as individuals; it was the system which was wrong, and he maintained that it was a position which ought now to be held by whole-time officers. He had been prepared for Prof. Macqueen's destructive criticism, but it had not altered his views in the slightest degree, he was glad Prof. Macqueen was satisfied. He still maintained that the social and scientific status of the profession was far from being on a proper or satisfactory basis. He had suggested remedies to every one of his complaints. He considered the main responsibility of raising the status of the profession as a whole rested with the Council. If according to Prof. Macqueen the Council had nothing else to do but to attend to examinations and to disregard other matters, he thought it was not to be wondered at that the profession took no interest in the elections, and the sooner they organised outside the Council the better. Prof. Macqueen had rather inferred that a personal attack was being made upon the Council. He (Mr. McIntosh) hoped that impression would not get about. He had the greatest respect for the members of the Council, and he had the greatest admiration for the work done by the present President, and he should be sorry if anyone went away with the idea that there was anything further meant than a criticism of the Council's constitution and its policy. Prof. Macqueen had said that so far as the profession was concerned the status of the profession rested entirely with the individual. There was no doubt that the status of the individual very largely rested with himself, but the status of the profession did not. It did not occupy as a profession that position in the scientific world that it ought to occupy. Prof. Macqueen had not offered any constructive policy, which was what was wanted. Mr. Slocock had referred to the annual meetings and asked why it was that there was such poor attendances. He (Mr. McIntosh) had been to those annual meetings and had got tired of going. There had been nothing to interest him; and he thought that was the feeling of most members. Mr. Slocock had thought the good work of the Council was not taken sufficiently into account. All recognised that a great deal of important and good work had been done by the Council; but it was the work the Council had not done that the members wanted criticised. He did not object to teachers on the Council, in fact he thought the schools ought to be represented *ex officio*; but one was bound to admit that if there was a large number of teachers on the Council there was a sort of underlying and directing force attached to their work which would have its influence in the Council Chamber. The profession did not want too much of that. With regard to the President's remarks, what he (the speaker)

objected to was the veterinary surgeon having to report matters through a lay individual, whether that individual was an agricultural or any other expert.

There was a large staff of laymen at present going round the country supervising the work of veterinary surgeons, which was wrong and a waste of public money. Those laymen were getting perhaps £500 or more a year, whilst the junior members of the veterinary staff in the same department were getting from £260 upwards—less than the chief typist in the same office. Was that State recognition? Who was to blame for that?—not the individual.

On the motion of Mr. Willett, seconded by Captain Angwin, a hearty vote of thanks was accorded to Mr. McIntosh.

Captain ANGWIN pointed out, in regard to the matter of meat inspection, that in the army the veterinary officer was allowed to do that work—not the medical officer.

A vote of thanks was also accorded to Dr. Leiper for bringing forward his morbid specimens.

HUGH A. MACCORMACK, Hon. Sec.

# EASTERN COUNTIES VETERINARY MEDICAL SOCIETY. [NATIONAL V.M.A.—SOUTHERN BRANCH.]

## ANNUAL MEETING.

The Annual Meeting was held on Saturday, February 15th, at the Bell Hotel, Norwich, Mr. H. V. Low, M.R.C.V.S., the President, in the chair. Other members present were:—Messrs T. Barcham, Paston; J. Godbold, Stowmarket; F. M. Wallis, Halstead; H. Downe, Diss; A. Holl, New Buckenham; H. Buckingham, Norwich; J. Buckingham, Harleston; S. Hill, East Rudham; J. M. Currie, Lowestoft; R. C. Baxter, Downham Market; J. Barr, Acle; E. Margaron, Swaffham; J. K. Gooch, Holt; D. Jack, Kings Lynn; H. P. Standley, Norwich; Hon. Sec., W. H. Dennett, Foulsham. (visitor)

Letters responding regret at inability to attend:—E. H. Leach, Newmarket; P. Turner, Ixworth; H. B. Nixon, Haverill; C. C. Nesling, Framlingham; E. A. Hudson, Barrow; A. P. Burgon, Haverhill; F. Gooch, Stamford; H. Wilkinson, Martham; W. Turtill, Wickham Market.

The HON. SECRETARY (pro tem) Mr. H. P. Standley read the minutes of the last meeting.

Mr. S. E. HILL, of Rudham, Mr. J. M. CURRIE, of Lowestoft, were elected members.

The HON. SEC. presented the accounts for the year 1918, which showed a balance at the bank at the end of the year of £31-18-8. The accounts were adopted.

## ELECTION OF OFFICERS.

*President.* The HON. SEC. said it was usual to elect one of the Vice-presidents as President, and he moved that Mr. J. Barr, of Acle, be President for the ensuing year. Mr. Margaron, (Swaffham) seconded the motion and it was agreed to.

*Vice-presidents.* The following were elected:—Messrs H. V. Low, Norwich; J. J. Scott, Colchester; G. A. Hudson, Barrow; M. Bray, Docking.

*The Committee* were elected as under: Messrs T. E. Barcham, H. P. Standley, M. Bray, H. Buckingham, J. Gooch, H. V. Low, and A. Holl junior.

*Auditors.* Messrs. Barcham and Buckingham were elected, on the motion of the chairman, seconded by Mr. Margaron.

*Hon. Secretary.* The Chairman invited Mr. H. P. Standley to act as Honorary Secretary for another year, and remarked that that gentlemen had done really good work in keeping the Society going during very hard

times. At the end of the year, when he hoped the Society would have been put upon a sounder basis they might be able to release Mr. Standley, who did not really care for the position; but in the meantime they could not afford to dispense with his services.

Mr. STANDLEY said he would accept the position for another year on the distinct understanding that he would be released at the end of the year. The members did not give him any encouragement to continue the work. They ignored his notices, absented themselves from the meetings, and took no interest at all in the Society; and had it not been for Mr. Low and himself the Society would have ceased to exist before now.

There was a lot of work attached to the job: all he asked was that the members would attend the meetings now and then.

The CHAIRMAN endorsed the remarks of Mr. Standley, and said it was disheartening to the officers to call meetings and find only one or two members attending. He was glad to see so good an attendance that day.

Mr. BAXTER said war conditions had prevented members attending meetings.

Mr. STANDLEY was duly elected Honorary Secretary.

On the motion of the Chairman, seconded by Mr. Gooch, it was agreed to give ten guineas to the Victoria Benevolent Fund.

The HON. SECRETARY reported that Mr. W. S. King, of Burdett Road, London, had written to him saying "Will you please let me know if you have any decided views for the re-construction of the Royal College of Veterinary Surgeons, and if so would you stand as a candidate if nominated; if not can you please let me know the very best man in your area with good sound views whom we could nominate."

The CHAIRMAN thought the Eastern Counties Society ought to be represented on the Council; but no member could be found willing to become a candidate, and the Hon. Secretary was instructed to reply to Mr. King to that effect.

The HON. SEC. read a letter from Mr. Coleman, of Swindon, asking for the support of the Eastern Counties Society for Mr. Male and Mr. Willett, candidates for the Council.

The HON. SEC. said that years ago the Eastern Counties Society used to join with the Yorkshire Society for the election of the members of the Council; and it might be well for them now to support Mr. Male and Mr. Willett, who were brought forward by the Royal Counties Veterinary Association, on the understanding that that society should in turn support any candidates the Eastern Counties Society might nominate at some future time. He proposed that this should be done.

Mr. BARCHAM seconded the motion and it was carried.

The HON. SEC. said Prof. Wooldrige had informed him that although the Eastern Counties Society was affiliated to the National Association, it had never paid any affiliation fees, and it therefore owed some £10 or £12.

Prof. WOOLDRIGE said the affiliation fee was 1/- per member per annum, counting only those members who had paid their subscriptions to their own societies. The war had greatly interfered with the work of the National and that was why no application had been made for the fees. There was much to be done once the National was got into proper working order, and a good deal of money could be usefully spent. He was acting as Treasurer and Secretary, but Colonel Brittlebank was really Secretary, and would do some really good work as soon as he was discharged from the army.

The HON. SEC. promised to find out how much is owing to the National, and to remit the amount as soon as possible.

The HON. SEC. submitted some correspondence on the subject of fees charged to insurance offices for inspection and examination of horses, etc., the rates hitherto paid

being unsatisfactory. In a letter dated Feb. 11, Mr. H. E. Howlett, Secretary of the Live Stock Offices Association wrote:—

"In reply to your favour of the 8th inst, it was mentioned at the last meeting of the Association on the 17th ult. that applications were being received from a few associations for higher fees for insurance inspections. As there is no body representing the whole of the veterinary profession in such matters, it appeared difficult to deal with the matter satisfactorily, but some members proposed that the associations which had suggested alterations should be notified that my Committee would be glad to hear the views of any representative appointed to attend at the next meeting of the Committee. I sent a notice to your Association as one member stated that it had issued a scale of fees, and as you stated on the 31st ult. that your association had not formulated any scale of increased fees, the matter seemed closed so far as your association is concerned. I may state that the meeting arranged for the 7th inst, was unavoidably deferred, and the only association that intimated that its representative would attend was advised of the alterations. The great difficulty is that while expenses are greatly increased the companies still charge pre-war rates."

To this Mr. Standley had replied "I cannot see any useful purpose that would be served by sending a member of the association to meet your association at the present time, as the E.C.V.M.A. has not formulated any scale of increased fees in connection with the Live Stock Cos. We shall be holding a meeting of the E.C.V.M.A. on Feb. 15th, and I will let you know the decision of the matter."

The Hon. Sec. said he had given notice to several insurance companies that he would not act for them unless they paid him 1/- mileage in addition to the present fees, and two other members of the society had taken the same stand.

Prof. WOOLDRIDGE said had he known this matter was likely to be brought up he would have brought with him some correspondence he had had with the Live Stock Offices Association. Just before the war the National took up very strongly this matter of fees for inspection for insurance offices, and formulated a scheme and a scale of fees. The scheme was discussed very thoroughly and the rates first drawn up were cut down until they could not be reduced any lower, so that they might meet with the approval of the insurance offices. Finally it was decided to circulate the scale of fees and to ask all members of the National to accept no work for the insurance companies except on payment of those fees. The Insurance Offices Association, however, did not accept the scale *in toto* but said the fees were higher than they could possibly pay; and no doubt they felt they could always find some veterinary surgeon who would do the work for lower fees, therefore the scale was never definitely established. Meantime the Gloucestershire Veterinary Surgeons Association had adopted a very concise and short scale of fees. This revived the matter with the Live Stock Offices Association, who decided, apparently, to go into it more thoroughly. They invited the Secretary of the National Veterinary Association, Col. Brittlebank, to meet them but he was on government service, so the letter was delivered to him (the speaker) who had also received a letter from the Gloucestershire Society asking him to represent them. He went as representing the National. He contested the statement in Mr. Howlett's letter to the effect that there was no representative body, and claimed that the National was a representative body for that kind of work. It was just the kind of work the National wanted to do, and in order that it might represent all Societies it asked them to become affiliated. Only by such an organisation could the veterinary surgeons obtain concerted action.

He suggested that the Hon. Secretary should write to the Live Stock Offices Association telling them they were affiliated with the National, and that their views would be put forward by the National at the joint meeting; and that they were prepared to abide by any agreement arrived at by the National. If the Eastern Counties Society chose to send a representative, no doubt he would strengthen the hands of the National. So far as he knew at present Mr. Adams of Gloucestershire and himself were the only two people who were likely to be at the meeting next Friday. At the last meeting of the National in January of this year the matter was brought forward again and it was decided that the fees suggested by the insurance companies should not be accepted, because they were below the scale already agreed upon by the National.

Mr. BAXTER thought this was a matter that needed pushing.

Prof. WOOLDRIDGE thought the insurance offices would give in if the veterinary surgeons persisted. The representative of one of the biggest insurance offices had told him that half-a-crown was ample payment for just looking at a horse; and he had retorted that perhaps it was, but mere inspection would not help the insurance company much. There must be an examination if any good was to be done.

No professional man ought to be satisfied to sign a form on a mere inspection. He ought to insist on carrying out an examination and being paid for it, in which case he would be performing a function that would be useful both to the insurance company and to the owner. That was the only sound policy a professional man could pursue.

Mr. BAXTER said the insurance companies declared they did not want an examination. They only wanted to be safeguarded against having an old screw passed on them as a sound horse.

The Hon. Sec. said they had to consider the journey. The insurance companies were rich, and there was no reason why they should not pay proper fees. It was up to the Society to pass some definite resolution and to adopt a minimum scale of fees.

Mr. BAXTER said he too had received an offer of 4/- from the Imperial, and had refused to accept it. About a week ago he had another letter saying he need not trouble about inspection, as they had accepted the horse without. He would have had to travel three miles to see the horse.

Mr. GOOCH said he that morning received a form asking him to examine two horses. Hitherto the scale of fees was always printed on the back of the form but the back of the one he received that morning was blank. He had been told that the fees were to be revised.

Mr. WALLIS said he knew of a case in which a young fellow inspected a horse for half-a-crown, and it died very shortly afterwards. The company should have paid more money and had the horse properly examined—as it was they incurred a heavy loss. He thought if the Society got Prof. Wooldrige to represent it at the meeting on Friday it would be in good hands. He was sure the members of the Eastern Counties Society would be satisfied with the scale of fees suggested by the National.

The Hon. Sec.: I think we ought to formulate a scale of fees for ourselves.

Mr. WALLIS: I should be prepared to accept the scale adopted by the National.

Prof. WOOLDRIDGE suggested that all societies ought to have the same scale of fees. There would be strength behind uniformity.

The Hon. Sec.: We do not know what the National scheme is.

Prof. WOOLDRIDGE said the matter had been thoroughly discussed by the National with the Insurance Assoc-

iation. The decisions come to seemed to meet the approval of a large majority of the profession.

The Hon. Sec. : That is good enough for us.

It was agreed that Prof. Wooldrige should represent the Eastern Counties Society at the meeting with the Live Stock Offices Association.

On the motion of Mr. Wallis it was agreed to hold the next meeting at Ipswich.

On the motion of the Chairman, the Hon. Sec. was instructed to send letters of condolence to Mrs. Measures Chatterton of East Rudham and Miss Cleveland of Bungay.

(To be concluded.)

### LAMINITIS IN PREGNANT EWES.

A client of mine asked me in a casual way to look at his flock of in-lamb ewes, which he said had gone off their feet. I found a flock of 165 Kent ewes just ready to lamb, well bred and in excellent condition.

The account he gave was the ewes had been close folded on swede turnip grown with artificial manure, when several became ill, feverish, and some died; others not so ill went lame on their feet; and that he had treated them with Epsom salts. There were about 20 showing lameness, principally in one foot; on examination no lesions were apparent, but pain on pressure and heat. The wool also looked rough and untidy, as if they had been ill. Of course, we know that swede turnip are dangerous to pregnant ewes if given *ad lib.*, also that exercise is very beneficial. My reason for sending you this brief account is that I do not remember meeting with a similar case.

CHARLES MORGAN, M.R.C.V.S.,

Nonington.

### INSURANCE FEES, ETC.

Mr. Bibbey's letter touches on a subject that affects many veterinary surgeons; but there are scores of Insurance Companies that will not pay half 10/- for visits and examinations. Recently I was asked to drive over 5 miles, examine 2 horses, and fill up a voluminous report for the magnificent sum of 6/-! Needless to say flat catching may be interesting but it necessitates the presence of a flat. The men who work for less than rag and bone merchant's or pedlar's fees ought to be earmarked.

It takes professional men to estimate justly the value of professional services. Draw up minimum fees, plank them before the Insurance Companies, and make it "conduct disgraceful in a professional respect" to work for less; and let it go at that.

If "Fra Diavolo" will reveal his name to the communication where he charges the army authorities with failing to cure sarcoptic mange until they used a proprietary dip, I think he will stand a good chance of an action for libel.

G. MAYALL.

F. W. DAY, M.R.C.V.S., Newmarket, Suffolk.

Graduated, Lond: April 1878.

Mr. Day died 11th March, aged 64.

The remains of the late Mr. F. W. Day, were interred in the Newmarket Cemetery on Saturday afternoon, 15th inst., amid every expression of esteem from those who have been his fellow townspeople for the last 30 years. The mourners included Mr. Reginald Day and Mr. Alec Day (sons), Mr. Elijah Moore and Mr. Charles Heckford (sons-in-law), Mr. Joe Cartwright and Mr. T. W. Davis (nephews of Mrs. Day). Mr. John Watts (son-in-law) was unavoidably absent. There were others who followed, and many present at the graveside.

## AMPUTATION OF THE UTERUS.

Mr. L. M. Magee recently, not for the first time, put a successful case of this operation on record; and some of the remarks upon the subject made by himself and other Irish members should be useful to country practitioners. The operation has never received quite the attention it deserves from English members. There have been men who considered it practically or absolutely hopeless, and there are still some who never attempt it. Yet it is certain that it offers considerable hope of success under fairly favourable conditions, and that not uncommonly it presents the only chance of saving the animal's life. These reasons alone should impel country practitioners in particular to study the operation; especially as, if performed at all, it always has to be done at short notice with no time for reading up its details.

There are several "pitfalls" in connection with the operation. The chief of these are the dangers of excising a hernia of bladder or intestine within the inverted uterus, of including the meatus urinarius in the ligatured portion, and of applying an insecure ligature. The first, which has caused many fatalities, can easily be avoided by incising the uterine mass and manually exploring its interior, while correct anatomical knowledge and wise choice of surgical method respectively should guard against the second and third. These three points show the risk of attempting the operation without having previously thought out its details.

The operation holds possibilities of interesting and important developments of its methods. It is not always necessary, and may even be inadvisable, to excise the entire uterus when only a portion has been hopelessly damaged; and this affords considerable scope for judgment in some cases.

A more important question is whether the uterine stump should be ligated or sutured. Ligation is almost universally practised; but W. L. Williams, the noted American surgeon and obstetrician, has advanced strong reasons, as regards the larger animals at least, for preferring suturing as "more surgical and safer," and has described the technique for its performance.

Partly because the operation is an old one, and still more from the conditions under which it is found necessary, the tendency has always been to perform it in a somewhat rough-and-ready fashion. Despite that fact, and the further one that it has not uncommonly been performed too late, it has been fairly successful. Probably further developments in its technique may improve its results in the future; but, even as it stands today, it is one of the operations which the country practitioner should keep himself fitted to perform at any moment.

## THE THERAPEUTIC EFFECTS OF INGESTING BLOOD OR PREPARATIONS OF BLOOD.

The therapeutic effects of ingesting natural blood have been known for a long time. The reason that this remedy has not been more used is that the majority of herbivorous animals, and especially mankind, have a very marked aversion to fresh blood, whatever its origin. Attempts have therefore been made to transform blood into a solid product which can be durably preserved; and the most advantageous results have been obtained by desiccation at a temperature below 40 °C. Goslar, a veterinarian, has perfected this method by, before desiccation, making an intimate mixture of blood and crushed grains. He thus obtains a solid clotted mass, the toughness of which results from the combination of gluten and fibrin, the whole forming a material of horny consistence. The product is not at all hygroscopic, and can be preserved almost indefinitely. An analogous compound, more especially destined for human therapeutics, is made by the same procedure and known under the name of "secron." On account of the low temperature at which the desiccation is carried out and the mixture with farinaceous material, the blood preserves almost intact all the biological properties which it owes to the presence of the ferments and enzymes secreted by the hæmatopoietic glands.

The principal glands of internal secretion which throw their products into the blood are the Thyroids, Supra renal Capsules, pituitary gland, and sexual glands. These organs may become diseased, may atrophy, or may degenerate, especially where there is superabundance of toxic material carried in the blood. This is observed frequently in cases of infectious disease, chronic intoxication, permanent bad digestion, etc. The hæmatopoietic glands are overworked, and finally no longer suffice for their task. It is comprehensible that in similar conditions, the ingestion of natural blood, or of a preparation in which blood coming from healthy animals has preserved the whole of its biological properties, may assist the distressed organism by supplying it with the ferments and anti-toxins which it is no longer able to elaborate for itself in sufficient quantities.

Goslar has given a *résumé* of the results obtained in human and veterinary medicine by the use of "secron" or a similar product.

The administration of secron to women suckling their infants causes a manifest augmentation of the sudoriparous, renal, and mammary glands.

Secron is also very efficacious in cases of dyspepsia or of intestinal catarrh. Gaseous indigestion of the human stomach recovers in a short time by the absorption of secron.

The activity of the skin augments very manifestly

under the influence of this treatment. In animals, the shedding of the hair is accelerated, and eczema and pruritis disappear after a short time.

This remedy is entirely indicated (and has proved its efficacy) against anæmia, chlorosis, suppression of the menses in women, and neurasthenia.

Secron has given marvellous results in the convalescence of horses after strangles or infectious pneumonia.

All this seems, at first sight, an exaggeration. Physiologically, however, the beneficial effects of the ingestion of blood or secron are easily comprehensible. It is only necessary to think of the important part which the hæmatopoietic glands play in the organism, and of the serious consequences which result from insufficiency of one or other of these glands. Organo-therapy or, in its absence, the absorption of integral blood is the only remedy for such insufficiency.

#### COCCIDIOSIS IN THE GOAT.

As coccidiosis of the goat had never previously been reported in Germany, Karsten published his personal observations upon it in *Deutsche Tierärztliche Wochenschrift* for 1913. In August, 1912, he learned that an epizootic had broken out in a herd of goats at pasture. The affected animals contracted persistent diarrhoea, became progressively emaciated, and finally fell into a state of extreme weakness, which was usually terminated by death.

Post-mortem examination showed that the affection was intestinal coccidiosis. It was then recognised that it would have been possible to make the diagnosis during life, for the diarrhoeic faeces containing numerous coccidia.

Upon diagnosis, the animals were at once withdrawn from the contaminated pastures; and from that time the propagation of the disease was definitely arrested, and 50% of the affected animals completely recovered.

#### HYDROCHLORIC ACID POISONING IN THE HORSE.

Levens has published this observation in *Deutsche Tierärztliche Wochenschrift*. He fed two horses of his own with foreign oats and excellent hay, and soon noticed an ulcerous stomatitis and a slight gastro-enteritis. Suspecting the oats, he had them analysed; and the result proved Hydrochloric acid had been used to impart a good colour to the oats; and the excess of acid had not subsequently been washed away. Appropriate treatment was instituted as soon as the origin of the disease became known; and after four days the horses were out of danger.—(*Annales de Médecine Vétérinaire*).

W. R. C.

### NATIONAL VETERINARY MEDICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

#### VETERINARY SURGEONS' FEES AND INSURANCE COMPANIES.

At the last Annual general meeting of the National Veterinary Medical Association the question of veterinary surgeons' fees was discussed, and a resolution was passed recommending that all fees charged by veterinary surgeons should be increased by not less than 25%.

It was further resolved that the scale of fees drawn up after numerous committee meetings, and adopted by

the National in March 1914, for the examination etc., of animals for insurance purposes should also be increased by 25%. The schedule of fees was duly circulated in 1914, to the local branches of the National, but owing to lack of united action on the part of some members, and of veterinary surgeons not members of the association or its branches, the insurance companies have continued to get their work done at absurdly low fees.

The proceedings at some of the local societies show that there is now a very widespread feeling that those fees must be raised, but there is great danger of undermining the work of the National by separate action if care is not taken.

As acting secretary of the National, and with the able assistance of Mr. A. S. Adams, of Dursley, representing the veterinary surgeons of Gloucestershire, I have been in conference with the Live Stock Offices Association, the body which co-ordinates the policy of the Insurance Companies, with reference, *inter alia*, to veterinary surgeons' fees. Negotiations are in hand at the present time, but some difficulty is being experienced owing to the view expressed by the L.S.O.A. that the National only represents some of the veterinary societies, and not all. This is true only in so far as concerns a few recently-formed societies or collections of veterinary surgeons who have not yet affiliated to the National.

Under these circumstances, therefore, I would suggest that the various Branches of the National, and other local bodies, should postpone their proceedings pending some definite result of the present negotiations. It might also strengthen our hands if the local societies intimated to the Live Stock Offices Association, 17 Pall Mall East, S.W. 1, their adherence to the National, and their willingness to accept the parent body, the N.V.M.A., as their authorised agents in this matter.

I append the schedule of fees as adopted in 1914, together with the list of fees as affected by the 25% increase.

Scale of Fees as finally adopted by the Council of the above Association at their sitting on the 12th of March, 1914, for examination and report on general health, condition, age, colour markings, and approximate value of animals proposed for insurance:—

#### HORSES AND VALUABLE PEDIGREE CATTLE.

	Original N.V.M.A. Fees.	Amended Fees
(a) Single animal under the value of £50	5/-	6/3
Two animals " " "	5/- ea.	6/3 ea.
After the first two " " "	2/6	3/1½
(b) Single animal valued at £50, and under £100	10/6	12/-
(c) " " valued at £100, and under £250	15/-	18/9
(d) " " valued at £250, and under £1000	21/-	26/3

If more than two animals are examined, the third and all subsequent ones at half the above charges.

#### STORE CATTLE, ORDINARY MILKING COWS, ETC.

(e) Single animal	5/-	6/3
Two or more animals	per head 2/6	3/1½
(f) Special reports on illness, accident, &c.	10/6	13/-
(g) Post-mortem exams. and reports	21/- ea.	26/3
(h) Other stock, sheep, pigs, etc., in considerable numbers, by special arrangements.		

The above fees are for services rendered at the veterinary surgeons' establishment, or within the distance of one mile thereof. For allowance beyond one mile the following additional fees are to be charged in lieu of mileage:—

From 1 to 3 miles	1/-	1/8
" 3 to 5 "	2/6	3/1½
" 5 to 8 "	3/6	4/4½
Beyond 8 miles in proportion.		

GEO. H. WOOLDRIDGE.

PARASITIC MANGE IN THE HORSE.

By PROF. G. H. WOOLDRIDGE R. V. COLL: LONDON.

Mange is a skin disease caused by parasites belonging to the order Acarina and comprised of the families Sarcoptidae and Demodecidae. The parasites are all small and are mainly microscopic in size though some may be recognised as small moving points with the unaided eye.

In the horse three genera of Sarcoptidae may be met with, namely, *Sarcoptes*, *Psoroptes* and the *Chorioptes*, or *Symbiotes*, causing respectively sarcoptic mange, psoroptic mange, or chorioptic or symbiotic mange. *Demodecidae* are comparatively rarer in the horse, and when present may set up demodectic or follicular mange.

**Life History of the Parasites.** All the Sarcoptidae have a similar life history. The fertilized or ovigerous female deposits her eggs, which under favourable circumstances hatch out and liberate the larvæ which possess only three pairs of legs and are asexual. After moulting several times the nymphæ is liberated possessing four pairs of legs but still asexual. After further moulting the nymphæ gives rise to the adult sexually mature male, or the pubescent female. The females are always in excess of the males. The male then fertilizes one or more females and dies, while the fertilized female, after moulting, becomes the ovigerous female and deposits her eggs, thus recommencing the life cycle.

In the case of the *Sarcoptes*, the females burrow into the epidermis, forming channels or galleries, depositing their eggs as they go, the number averaging about 15 (10-30.) The *Sarcoptes* then perishes in the depth of the gallery. The eggs hatch out in from 3-7 days and the hexapod larvæ come to the surface, but are still protected by the scales of the skin. Under favourable conditions the larvæ become nymphæ 3-4 days later, and after a similar period the adults are produced from the nymphæ, the full cycle under favourable conditions thus takes from 2-3 weeks. Unless a considerable number of parasites were simultaneously transferred from a diseased to a healthy animal, it would therefore take at least three weeks before symptoms of mange would develop, while if the parasites were very few it would probably take another 3 or 4 weeks for the second generation of acari to be produced before any symptoms would be shown.

The *Psoroptes* live on the surface of the skin, under the scales of the epidermis, but do not burrow. In other respects their life history corresponds very closely with that of the *sarcoptes*, but as the female deposits many more eggs, 90-100, their multiplication is very much more rapid.

The *Chorioptes* or *Symbiotes* also live on the surface and do not burrow, and have a similar life history. They are limited to the legs of the host.

CHARACTERS OF THE PARASITES.

***Sarcoptes Equi.*** The sarcopt is a very small acarus round or oval in shape. The head or rostrum, consisting of maxilla, mandibles and palpi, is very thick and strong and adapted for burrowing. It possesses four pairs of short thick legs, the anterior two pairs being close to the head at the side of the body, and the posterior two pairs being under the body, the last pair being invisible from the dorsal aspect. In the female the first and second pair of legs carry bell-shaped suckers on short stalks, and in the male the first, second and fourth pairs carry suckers. The ovigerous female is about 400 microns long and the male about 250 microns.

***Psoroptes Equi.*** This is the largest of the mange acari, the ovigerous female averaging about 700 microns

long and the male 500 microns. It is oval in shape, and the rostrum is long and conical, and thus adapted for piercing the epidermis. The limbs are long and attached near to the margin of the body. The female carries suckers on the first, second and fourth pairs of legs, and the male carries suckers on the first, second and third pairs of legs. In the male there are also two triangular abdominal prolongations each carrying five hairs.

***Chorioptes Equi.*** The chorioptes are also oval parasites, the females being about 400 microns long and the males about 300 microns. They possess a short conical rostrum, but fairly long legs. The female possesses suckers on the first, second and fourth pairs, and the male has suckers on all four pairs, on very short stalks. The male also possesses two rectangular abdominal prolongations each carrying four bristles.

The duration of life of the various parasites is subject to much variation. On the host the probable duration is from 4 to 6 weeks after attaining maturity. Off the host the parasites live a much shorter time—the *sarcoptes* 7-14 days, the *psoroptes* 3-4 weeks, and the *chorioptes* rather longer, probably as much as 7-8 weeks. The eggs of the various parasites only retain their vitality for 2-4 weeks.

GENERAL SYMPTOMS.

These depend partly upon the mechanical irritation caused by the parasites puncturing the epidermis, or burrowing in the case of the *sarcoptes*, and also to some extent by irritating secretions which they produce; the latter is probably of far greater importance than generally recognised. The most noticeable features are intense irritation, which is usually worse at night time or if the animal becomes hot. There is loss of hair, redness of the skin visible in light coloured horses, and thickening of the epidermis with the formation of scales and crusts. If the affection is wide spread and chronic it will also lead to great emaciation and loss of flesh, due to interference with the functions of the skin, to lack of rest, and to the absorption of toxic products. In such cases it may terminate fatally.

***Symptoms of Sarcoptic Mange.*** The first sign is that of intense pruritus. The animal is constantly rubbing and biting itself, and if rubbed or scratched by the hand usually shows satisfaction by stretching the head and by peculiar movements of the lips and nose. One may also feel small papules on the skin, and scaly patches may be seen from which the hair soon falls. The patches which are small at first, usually commence about the withers, neck and shoulders, extend by rubbing and by grooming, and may eventually affect the whole trunk. The limbs, the mane and tail are very rarely invaded by the *sarcoptes*. On account of the rubbing etc, the thickened skin may become fissured, with the formation of bleeding crusts and nauseous discharge. If the condition is widespread and treatment is neglected there is great malnutrition wasting and debility, and it may be fatal.

***Symptoms of Psoroptic Mange*** are similar in many respects to those of sarcoptic mange. The lesions first appear about the mane and tail from which seats they spread along the back, then to the poll, the submaxillary space and the breast, and in bad cases may extend all over the trunk, but only in exceptional cases does it extend to the limbs. There is intense pruritus and the animal responds in a similar manner to rubbing with the hand. (It may be mentioned in passing, however, that this response to rubbing is by no means diagnostic of mange. It is only an evidence of pruritus, and horses affected with lice or harvest bugs, etc., will respond in a similar manner). In psoroptic mange there is often a little yellowish serous exudate on to the surface of the skin giving a moister and more matted condition than is usual in sarcoptic mange. It has been observed that in

some horses the psoroptes may be confined to the region of the ears without causing serious lesions. In such cases the animal often shakes his head and rubs it against the manger or other object and may attempt to scratch it with his hind foot.

The differences between the symptoms of sarcoptic and psoroptic mange in bad cases are comparatively slight and it is often quite impossible to differentiate them except by the discovery and identification of the individual parasite. Occasionally, of course, the two forms may co-exist. The importance of positive diagnosis lies in prognosis, since an earlier recovery may be expected in psoroptic than in sarcoptic mange.

*Symptoms of Choriopic or Symbiotic Mange.* This form is chiefly met with in the lower part of the limbs, the pasterns and fetlocks, and sometimes extending above the hocks and knees. It most frequently occurs in coarse, hairy legged horses, and dirt and neglect materially predispose to infection. Attention is often first drawn to the condition by the animal stamping his feet and rubbing his leg with the opposite foot, and the irritation appears to be more pronounced at night when in a warm stable. On examination, the skin at the back of the pasterns and fetlocks is seen to be scaly and thickened, and the hair may be rubbed off. The thickening of the skin often leads to the formation of fissures which usually contain exudate and offensive discharge. The great pruritus and consequent rubbing of one leg against the other leads to the formation of ulcers, and sometimes to injuries of the coronets resembling treads. Choriopic mange very rarely extends to any part other than the limbs, and the general condition of the horse is not much interfered with.

#### DIAGNOSIS.

The clinical features of mange are often sufficient to afford a basis for a fairly positive opinion without the resort to microscopic examination, but in no case should an *absolutely* positive diagnosis be made without the discovery of the causal parasite. Somewhat similar itchy conditions of the skin may be set up by lice, hay-mites and harvest bugs, and in each of these cases a horse will indicate pleasure by nibbling movements of his lips, etc., on being rubbed with the hand. The discovery of these parasites, however, does not definitely negative the existence of mange, but if they are present and a careful examination fails to reveal the presence of mange parasites it may be safely presumed that the former are the cause of the skin disease.

*Examination for the Parasite.* For this purpose scrapings from the skin of the affected animal must be taken from some new lesion which has not been treated with parasiticide dressings. A deep scraping should be taken right through the epidermis in order to ensure the removal of parasites from the deeper situations as in the case of sarcoptes. The scraping may then be warmed and examined with a hand lens by which psoroptes or choriopes may be seen. They may, however, be more easily seen by soaking the crusts in 10% caustic potash solution and then spreading it on a glass slide for examination under low power of the microscope. By this method the sarcoptes may also be seen.

Another simple method of examination consists in placing the scrapings in a small glass covered specimen box like a pill box and putting it in a warm place for half an hour or so. The warmth makes the parasites somewhat active and they often emerge from the debris on to the inner surface of the glass lid and can then be identified by hand lens or transferred to a slide for microscopic examination.

Pugh's mange tray is also a useful means of discovering the parasites. It consists of a black enamelled hot water dish. It is filled with hot water, and the scrapings are placed outside the tray. The warmth makes the

parasites active and they can be seen making their way out of the debris, either by the naked eye or by means of a hand lens. The black enamelled surface makes them easily visible. They can then be transferred to a slide for minute microscopic examination. These methods are, however, rather tedious in cases where the parasites are not numerous and a considerable quantity of material has to be examined. It is then that the method suggested by Sheather is particularly serviceable. In fact if a large number of scrapings has to be examined this is the most expeditious and certain method of discovering the parasite if present.

*Sheather's Method.* This consists of placing the material in a test tube (or a portion of, it as it may be wise to reserve a little in case of accident). Hair and epithelial debris may be all put in together. A quantity of 10% caustic potash solution is then put in the test tube and it is boiled over a Bunsen burner or spirit lamp from 5-10 minutes. This dissolves most of the hair and epithelium, but the parasites and their eggs are left uninjured. The material is then centrifuged for a few turns, as the result of which process any parasites present are speedily driven to the bottom of the tube. The sediment thus obtained should then be transferred by means of a pipette to a slide and spread out and examined under a low power of the microscope. Practically the whole of the parasites from a large amount of material may thus be obtained on a single slide, so avoiding the necessity of examination of numerous slides. The method is particularly serviceable in those cases where the parasites are not very numerous.

*Transmission.* The chief source of infection in mange is an affected animal and it often happens that an animal already affected is introduced into a stud but not showing appreciable symptoms for a month or two after. During this period his grooming utensils have been used on other horses and parasites have been transferred, so that by the time the first one shows symptoms there may be others also showing symptoms of mange. Other means of transmission include harness, hands and clothes of attendants, rubbing posts, litter, railway horse boxes and ambulances, and it should be pointed out that the blacksmith is anything but free from suspicion. Transmission is more rapid in studs where a number of horses are stabled closely together, and particularly in badly kept neglected horses and stables. Over-work, exposure and bad feeding afford better conditions for the development of the parasites when once they have been conveyed to the skin of an animal. The sarcoptic and psoroptic forms are the most easily transferred, while the symbiotic form of the disease is much less rapidly transferred.

Sarcoptic mange is transmissible from horse to horse and sometimes to the ox; it is also transmissible to man, and affects the arms and breasts of grooms and stablemen causing great pruritus. It only lasts a few days, and is rapidly remedied with a little sulphur ointment. Psoroptic mange is easily transmitted from horse to horse, but not to grooms. Symbiotic mange is also transmissible only from horse to horse and often then only in favourable or dirty conditions.

#### FOLLICULAR MANGE.

As already stated follicular mange, which is due to the *Demodex folliculorum* is sometimes met with in the horse. This parasite differs considerably from the sarcoptidæ already described. It is a degenerate form of acarid, with an elongated fusiform body having in the adult stage four pairs of short stumpy legs which protrude like little knobs at the margins of the anterior portion of the body. The species has a life cycle similar to that of other acari. The ovigerous females deposit eggs from which hexapod larvae are hatched. These give rise to nymphæ which are asexual and subsequently

develope into the sexually mature acari. They inhabit principally the hair follicles and the sebaceous glands of the skin, and sometimes set up lesions closely resembling acne. It is not a very contagious disease and its actual method of spread is obscure.

**Symptoms.** The lesions of follicular mange in the horse are principally met with about the head, chiefly in the region of the eye-lids and the nose. The hairs become erect and are often shed, and a scaly condition develops, pustules are comparatively rare. There is very little pruritus and it is rare for more than one case to be met with at a time.

#### TREATMENT.

The treatment of sarcoptic and psoroptic and follicular mange consists primarily in the application of parasitocides, a considerable number of which are effective. Thoroughness and frequency of application are the only secrets of success, provided, of course, that an efficient parasiticide is used; and herein lies the difficulty. If one wishes to be uniformly successful it would appear to be necessary to apply the remedies oneself, but in a large practice such a procedure is not practicable. Owing to the life cycle, the dressings should be applied every 4 days. For psoroptic and choriopic mange, 4 such dressings should suffice. For sarcoptic the treatment must extend over 4 to 6 weeks. The various parasitocides employed include sulphur, potassium sulphurate, sulphurated lime, creosote, oil of tar, turpentine, petroleum, crude tobacco juice, salicylic acid, arsenic, mercury, chloride of zinc, and eusol. It is difficult to say which of these is the most effective, for as I have already stated, probably more depends upon the method and thoroughness of application than on the choice of the particular agent. In my hands the best results have been obtained with the old dressing consisting of sulphur 1-1½ lb, bicarbonate of potash ½ lb, oil of tar 3viii and rape oil 1 gallon. It has been practically impossible recently to obtain good rape oil for this purpose, and other oils which have been suggested, such as fish oil and train oil, are rather apt to blister the skin and cause a shedding of the coat, which may be found very troublesome. The lime and sulphur dressing is a much cheaper preparation, and according to some authorities is equally effective, though in my hands it has not proved quite so useful. As recommended by the Board of Agriculture, it may be prepared by first mixing together 9lb lime, recently slaked, with 18lb sulphur, and making it into a paste almost like mortar. It is put into a cloth bag tied securely and suspended in a boiler containing from 10-12 gals. of water. It is then boiled for 2-3 hours, when it is yellowish brown in colour. If the water has become reduced to less than 10 gals. it must be made up to that amount. This concentrated solution may then be employed in the proportion of 1 pint to a gallon of water. In preparing the dressing the bag must not touch the sides of the boiler otherwise it would probably burn through and burst liberating the lime and sulphur and ruining the material and probably the boiler.

Another simple preparation consists in boiling together sulphur and washing soda in the proportion of 1lb of each to the gallon of water. Of the arsenical preparations Cooper's sheep dip may be used, or a crude Fowler's solution (1% white arsenic dissolved with the assistance of caustic potash). A mercurial soap is frequently used with excellent results: it consists of equal parts of strong blue mercurial ointment and soft soap melted together and thoroughly mixed. Of chloride of zinc a useful preparation may be made from Burnett's disinfecting fluid which contains 200 grs. to 3i by mixing 3xv-xx to a gallon of water, thus reducing it to either 4 or 5 per cent solution.

**Method of Application.** The animal should be isolated and a separate groom told off to look after the

affected animals. Wherever possible the coat should be clipped and the clippings should be burnt. The skin should next be well soaked and washed with soda and water and hard soap, to soften the scales as far as possible and thus allow the dressing to penetrate. The dressing should next be applied all over the body in the case of sarcoptic and psoroptic mange, owing to the impossibility of determining the exact limit of the spread of the parasite. The dressing should be repeated in four days and washed off at the end of a week. The skin should be left undressed for a few days, then the dressing repeated as before. In the case of psoroptic mange, if the dressings have been thoroughly applied practically all the parasites will have been destroyed, including those which have hatched out in the interval; so that in from 2-3 weeks in psoroptic mange all the parasites should be destroyed, and all that remains is for the hair to grow again. In the case of sarcoptic mange it is usually necessary to continue the treatment for a further similar period owing to the different life history of the parasite. The Board of Agriculture recommend the application of the lime and sulphur dressing by means of a spray, and suggests that by this method it is unnecessary to clip the horse, since if the spray is directed in the opposite way to the hair it will be driven close into the skin, and the thicker coat assists in the retention of more fluid and therefore is more effective in destroying the parasites. In my experience the application by this method requires assisting by rubbing of the lotion into the skin since most of the liquid runs off the coat as applied. A good plan and probably the best, is to give two dressings of the oil, sulphur, and tar, and use the spray for subsequent dressings twice each week.

During the course of treatment the exhaustion and emaciation must be counteracted by a generous diet and the administration of a course of tonics, including arsenic; but in bad cases in spite of all vigorous attention horses will become cachectic, weak and may die.

In France the method of treatment by fumigation with sulphurous acid gas has been recommended and good results claimed for it. After clipping and washing, the horse is placed in a loose box with his head protruding through a tarpaulin sheet; otherwise the box is as nearly air-tight as possible. A quantity of concentrated sulphur dioxide is then turned on into the box and the horse is kept exposed to the gas for two hours. The head is subsequently dressed with a 10% solution of creosyl in oil. The cure is said to be effected fairly rapidly by this method.

**Symbiotic Mange.** Owing to the more limited distribution of this form the treatment is simpler than that of the other forms of mange, but the same dressings will be found equally effective. Wherever possible the hair should be removed from the legs first, and the application must be repeated several times with intervals of a few days.

A very important part of the treatment for mange consists in the attention to the stables, clothing, harness, grooming utensils, and any place on which an animal may have rubbed, including the shafts of the various vehicles. These should all be very thoroughly disinfected. After which the stalls and boxes well swept out and the sweepings burnt. For disinfection of the premises the Board of Agriculture recommend a thorough washing with a 4% minimum solution of carbolic acid containing not less than 95% of actual carbolic acid. It should be pointed out that lime wash is of itself not a disinfectant, and that to be effective it should contain not less than 4% of carbolic acid. The clothing, harness and utensils should all be exposed to a similar potent parasiticide in a large tank. Any half-hearted attempt at disinfecting these articles is fore-doomed to failure.

Relapses after apparent recovery from mange not infrequently occur. A few parasites may survive the

treatment, but as they take a long time to become sufficiently numerous to cause fresh symptoms the relapse may not be apparent for several months. It is therefore doubtful whether an apparently recovered animal should be reintroduced into a healthy stud in less than three months. It may not, however, be practicable in many cases to carry out this principle.

It is well to point out that although the measures recommended for the treatment of mange appear to be comparatively simple, those who have had much experience of the disease know full well that they are by no means as simple as they appear, and that with all care results are frequently very disappointing. There appears to be no royal road to success; thoroughness, patience, and perseverance, together with a judicious use of parasiticides, will, in the majority of cases, be rewarded by success.

In answering questions that followed the reading of the paper, Prof. Wooldridge said he knew of no cases in which horses had caught a chill after being dressed all over.

The CHAIRMAN said he quite agreed that the old tar, oil, and sulphur dressing was most effective.

Prof. WOOLDRIDGE answering other questions said he had sometimes found lice and the mange parasite on the same horse. Generally the mane and the tail ought to be clipped in the case of parasitic mange. It was not practicable to take all the hair off a horse's tail as a rule but if that was the only way by which good results could be obtained by all means let it be done, because it would expedite the cure. It was more difficult to treat in the mane than in the tail, although there was likely to be a good deal of trouble at the base of the tail. He much preferred rape oil to train oil.

Mr. WALLIS: I have used a good deal of train oil and never found it do any harm.

Prof. WOOLDRIDGE: I have used it and got blisters.

Mr. WALLIS: The pre-war train oil never did that.

The Hon. Sec.: But the war train oil does.

Prof. WOOLDRIDGE: Even the rape oil is not so good as it used to be.

Mr. WALLIS: What about linseed?

Prof. WOOLDRIDGE: It is a drying oil and blisters the skin. An ideal oil would be olive oil, but it is far too expensive.

Mr. WALLIS: Will train oil and rape oil mixed do?

Prof. WOOLDRIDGE advocated the use of eusol as the finest and cheapest solution. It was perfectly safe and non-poisonous. It could be used on the frailest dog and cat, on any sort of wound, and to swab out the peritoneal cavity. It could be used in eye and in ear cases. It would sweeten the most stinking wound in a few moments. It was made of 1oz. chlorinated lime, 1oz. boric acid, and water to one Winchester quart. It must be filtered after three hours when it would become a perfectly clear water-like solution. It would keep potent for several months if properly corked up. At the College he used more of that than of all other disinfectants put together. They must not, however put their instruments into it. It turned blood green.

Mr. WALLIS mentioned that some weeks ago he had a fire in his office and discovered that drugs and instruments in his house were not covered by his fire policy. He mentioned this for the information of members. As an old insurer the company paid him, but they were not bound to do so.

After reading the paper, Prof. Wooldridge exhibited under the microscope the various types of mange parasites, and also specimens of the harvest bug, horse lice, hay mites and meal mites, fowl acari, and stained sections of hair affected with ringworm.

He also exhibited a spraying pump of the kind recommended by the Board of Agriculture.

A hearty vote of thanks was unanimously passed by the members present to Prof. Wooldridge for coming down and giving them such a splendid paper, which the Professor briefly replied to.

HY. P. STANDLEY, Hon. Sec.

#### NORTH OF IRELAND VETERINARY MEDICAL ASSOCIATION.

##### RESOLUTION.

Passed unanimously at a General Meeting of the members of the North of Ireland Veterinary Medical Association, held at Belfast, this 28th day of March, 1919:—

"That this meeting place on record its appreciation of the action of the Government in introducing the Ministry of Health Bill, and its application to Ireland. Further, having regard to the invaluable assistance heretofore rendered by the members of the veterinary profession to the cause of public health, and to the important part which they must in the future undertake in the matter, would point out the necessity of having the words 'And a member of the Royal College of Veterinary Surgeons' added to clause (d) of subsection 2; and at least one member of the veterinary profession on the Irish Public Health Consultative Council; and this meeting requests the Government to provide in said Bill for such representation.

That copies of this resolution be forwarded to the Prime Minister, Dr Addison, the Chief Secretary for Ireland, the Attorney General for Ireland, and the Ulster Members of Parliament."

Belfast, 31st March, 1919.

#### GLASGOW VETERINARY COLLEGE.

At a meeting of the Board of Governors of the Glasgow Veterinary College held in Glasgow, Sir Hugh Shaw Stewart, Bart., C.B., presiding, a report was submitted by the representatives who had attended the recent conferences held at the office of the Highland and Agricultural Society in Edinburgh regarding the proposed national scheme for research into diseases of animals. The report stated that there were present representatives from the Highland Society, the Scottish Chamber of Agriculture, the National Farmers' Union, and the two Scottish Veterinary Colleges, and that subsequently these representatives had conferred on the subject with the Board of Agriculture at the office of the Board, who were in full sympathy with the scheme.

It was decided to hold an opening lecture at the College at the commencement of the new session in October next, and it was left to Professor Glaister of Glasgow University, and Professor Gaiger, of the College, to make the necessary arrangements. No opening lecture has been held since the commencement of the war.

#### VETERINARY POLITICS.

Sir,—This week's *Record* is very depressing reading. Nearly all its space is taken up with the reports of the Eastern Counties and Central Societies, and what did their proceedings amount to? The Eastern Counties' men were bad enough. They were largely occupied in discussing the eternally recurrent question of insurance companies' fees; but, as usual in veterinary debates upon this subject, there was little evidence that anyone realised certain obvious truths which will *always* prevent insurance companies from offering terms really satisfactory to the profession. The members of the Central Society were still worse. They were discussing,

"the situation of veterinary politics," and how much clearer did they make it? Many "grievances" were enlarged upon, but how many suggestions to remedy them were put forward? There was plenty of talk of what ought to be done, and too little thought of what could be done. I have never read a series of more strikingly futile speeches, and none were much more so than those of the two candidates for Council. The collective wisdom of the meeting may be judged from the fact that the retrograde scheme of "district representation" received universal approval. How that proposal, if it could be carried into effect, could be expected to remedy existing "grievances" is beyond comprehension; and certainly it would tend to put smaller and narrower men on the Council. The system of societies running candidates for the Council has given us many mediocrities and some nonentities; that of district representation would give us a still larger number of both. The only good thing to be said of district representation is that it is not so dangerous as another policy which was advocated at the meeting, and recently also in other quarters—the policy of a veterinary strike. It is time for us to ponder where *that* advice is likely to lead us.

On March 22nd you published a letter signed "Fra Diavolo," which was a most curious mixture of very bad and very good advice. The bad, of course, was that we should return to advertising, and lose most of our professional status by adopting trade methods. The best part of the good is the single sentence "If members of the profession had the instinct for combination so highly developed in miners, *still they could be done without.*" The italics are mine, and no wiser words than those could be spoken to the profession just now.

For we *could* be done without. We are a useful body whose utility is not yet fully recognised; and, even if it were, we are not and never shall be indispensable. Insurance companies, upon whom we so urgently press our claims, could do without us. Some, including, I think, at least one of the largest, do so now; *all* will if we insist upon terms that would make their contracts unprofitable. The public could do without us; we know that many owners habitually do so, and more will if we persist in demanding more than they think we are worth. Let us remember that veterinary schools and trained veterinary surgeons have only existed a few generations, that for by far the greater part of the world's history all veterinary work was done by empirics, and that throughout that period the work itself was more important economically than today—and let us be warned in time.—Yours faithfully,

"DAGONET."

#### COUNTY COUNCIL FEES AND MILEAGE.

To the Editor of "The Veterinary Record."

Sir,—May I appeal through the medium of your Journal to secretaries or other members of Veterinary Medical Associations as to what the County Council fees and mileage are in the counties they embrace, as there appears to be a great diversity of charges; we in the west do not think we are being paid sufficiently and would like to know what other counties are receiving. I do not see why there should not be a universal fee throughout the country, and if our "Veterinary Parliament" would take this matter up and the question of fees generally, I am inclined to think the subscriptions to the R.C.V.S. would increase very considerably. A post card reply will oblige. Thanking you in anticipation.—Yours faithfully,

WM. ROACH.

President Western Counties V.M.A.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919:—

Mar. 25.

H. Andrew, London, S.W. 1.	£1 1 0
T. J. Brain, Cheltenham.	1 1 0
J. J. Crowhurst, Stratford-on-Avon	1 1 0

Erratum.—In the list appearing on March 22nd, the subscription entered from "A. L. Farrant, Hove," should have been entered "A. L. Farrant, Major, C.M.G. Corps."

### ARMY VETERINARY SERVICE

Buckingham Palace, Mar. 20.

His Majesty held an Investiture in the Ball Room of the Palace at 11 o'clock.

The following were severally introduced into the presence of The King, when His Majesty invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted:—

THE MOST DISTINGUISHED ORDER OF  
ST. MICHAEL AND ST. GEORGE.

Col. WILLIAM ANTHONY. Lieut.-Col. ALFRED HEAD.

### OBITUARY.

JOSEPH WOODGER, M.R.C.V.S.,

Graduated Lond: May, 1860.

Mr. Woodger died on 26th March, at 60 Sutton Court Road, Chiswick, aged 79.

DELANEY, GEORGE JOSEPH, M.R.C.V.S., Ballyhaunis, Co. Mayo.

Graduated Dub: Dec., 1914.

Died November, 1918.

The late Mr. K. P. Rankin.

Mr. Kenneth Rankin, inspector Board of Agriculture and Fisheries, was the fourth son of late Rev. Robert Rankin, B.D., of Lamington. Mr. Rankin was held in very high esteem. He was a faithful and trusted officer of the Board of Agriculture, thoroughly conscientious, and having a wide veterinary knowledge, which he applied with caution and firmness. Prior to his death he was investigating the serious outbreak of rabies in the South of England.—N.B.A.

CASE—On March 24th, at Cobham Lodge, Munster Road, Fulham, Queenie, the darling only child of Mr. and Mrs. A. Case, aged 9 years. After 5 days illness.

### Personal.

MOORE—Lily Mary Patricia, wife of Captain Roger Moore, R.A.V.C., of a son, at Harrington Square, 26th March.

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1605.

APRIL 12, 1919.

VOL. XXXI.

## THE ROLE OF "THE NATIONAL."

One of the most hopeful signs of the changing conditions at the present time is the resumption by the National V.M.A., of its normal functions, which have necessarily been in abeyance during the absence of so large a proportion of its members.

In our issue of last week, Prof. Wooldridge described the action of The National V.M.A. with regard to insurance companies' fees, and asked local societies to take certain steps to strengthen the hands of the central body. In the same number Mr. Roach, the President of the Western Counties V.M.A., asked other local societies for information concerning County Council fees and mileage. He did not mention the "National," to which his own society is affiliated; but obviously the "National" could be quite as useful in dealing with County Councils as with Insurance Companies. It is more than questionable whether the Council R.C.V.S. would concern itself with either question, and reasons can be advanced against such action. The "National" could undertake both; and, with its organisation, should be a much more effective instrument for any such work than the College Council.

A uniform scale of fees throughout the country covering all the requirements of general practice is a more than doubtful proposition: the difficulties of establishing such a scale are great. Uniformity as regards some special branches, such as County Council or Insurance work seems much more feasible. The "National," from its extensive local connections, could do excellent work towards this end; but in this, as in all questions of fees, the support of the profession is essential. It is necessary to be made clear that the "National" is representative of all the societies. Prof. Wooldridge indicates that some difficulty on this score has already arisen in the negotiations upon insurance fees, and offers useful suggestions to remove it. The same point might arise with County Councils, and could be met in the same way. At present the "National" is not unassailable in this respect, but the local societies could soon make it so.

Another difficulty may prove much more serious. This is what Prof. Wooldridge euphemistically calls "lack of united action on the part of some members, and of veterinary surgeons not members of the association or its branches." This factor may not have much, if indeed any, effect as regards County Councils; but it is clear that it must be reckoned with as regards Insurance Companies. The first and best method of dealing with it is by working to increase the strength and influence of The National and all its branches.

## THE REGISTER R.C.V.S.

Copies of the Register for the current year are now issued. Like its predecessor, it is a "war" issue, shorn of much of the supplementary information which we have grown accustomed to look for in late years; but it is hoped that next year there will be a return to better conditions. The number of names registered is 3359, against 3381 of the last issue; and this includes 22 names of members whose present address is unknown to the Registrar. Members who can assist in the matter are asked to send the information to 10 Red Lion Square. In this connection it should be remembered that entry on the Register—not the possession of the diploma—is the legal evidence of qualification to practise (V.S. Act 1881, Sec. 9).

The list of members admitted since last issue contains 44 names: and the obituary list has 67 names, of which 16 were deaths while "on service." There are also the names of Prof. A. Degive, and Prof. A. Liautard, Honorary Associates R.C.V.S.

Recent reports of Council meetings show the probability of an increasing number of entries of students at the Veterinary Colleges, but obviously, several years must elapse before there can be any material increase of practitioners on the Register.

Register III—"Existing Practitioners," shows a decrease from 145 to 137 during the year, a rate which has shown little change for the past five years.

## ON PROPAGANDA WORK.

The very interesting address by Mr. J. W. McIntosh on "The situation of Veterinary Politics," and the discussion which followed, may well point a moral, and I think one can hardly emphasize too strongly some of the comments made by Professor Macqueen.

General complaints about the social position of the profession leave me quite cold. I can remember to have heard the same things nearly forty years ago. The forms change but they are all fundamentally the same. It appears actually that the social position of the veterinary profession is precisely that of any other profession, which is, that each individual member's social position is only personal to himself.

The political position is a very different matter indeed. In this sense the profession in France (I mention that country because I have been resident there for thirteen years) occupies a very good position indeed.

The position in most of our colonies is very satisfactory, and in Australia, in New Zealand and in Canada, the profession has a great deal of influence.

The political position in the United Kingdom seems to be generally admitted to be very unsatisfactory. I am one of those who believe our political position in this country to be entirely bad, and our influence very small; and I attribute this to the apparent fact that our existence is almost unknown to the public. To lead the life of a hermit is a luxury one must pay for sooner or later, and our general policy of obscurity has already pushed us to the verge of bankruptcy, and will, if continued, put us over the edge.

I agree with Prof. Macqueen that to blame the Council is unjust, since that body has no power in this particular matter except in the elimination of unfit elements, and in that matter it seems to be perfectly capable and zealous.

Prof. Macqueen said "What was required was propaganda work." I believe that to be the root of the whole matter, since every profession (except our own) and every institution (except our own) appears to advertise itself constantly, by means of printers' ink or with the aid of artists' work.

During my lifetime I have seen only one solitary account in the press of any British Veterinary College, which could be called in the least instructive or attractive to the public. This was a small article in the *Cornhill Magazine* (I think in 1882) on the work of the Royal Veterinary College, London. It was somewhat sketchy, but was well written, and illustrated with some good drawings by Corbould, the well known animal artist and illustrator. After that brief incursion into public life we subsided once more into more or less oblivion, and none of our Colleges or Veterinary establishments appear since to have imagined that the general public would be at all interested to hear anything about them.

The Army Veterinary Service is, and always has been equally a bad example, and this is further emphasised by the fact that most other branches of the Army have been constant subjects for the press and the illustrator, while it alone avoids the limelight.

Prof. Macqueen says we must first induce members of the profession to take an interest in it themselves. That is quite evidently the first thing necessary, and if they did so, and took a pride and a pleasure in the profession as such, they might also find a pleasure in taking the public into their confidence by means of every kind of propaganda work.

The danger of advocating propaganda work is its tendency to assume a spasmodic type. It should not consist of one spasm, such as happened in 1882, and then be dropped for thirty seven years. It is better to at once fall in with modern habits, and conduct our propaganda work in the various ways and with the constancy so admirably exhibited by most other professions.

At the present moment it is not too much to say, that the work of our Army Service, our Civil service, and our educational establishments, is to all intents and purposes unknown even to a large number of members of the profession. The dull reports occasionally issued are unfitted, and apparently not

intended for ordinary consumption, and are in any case seldom if ever read by anyone but the writers, and the printers.

The nature of our work, its vitally humanising interests, and its very picturesque surroundings, give us an opportunity for possibly far more attractive propaganda than can, in the nature of things, be enjoyed by almost any other profession. We have, and always have had the most priceless opportunities, of which, if we had ever taken even a small advantage we should certainly not now be complaining of lack of political influence or of public appreciation and sympathy.

The big public, either in this country or any other, cannot show understanding of, and sympathy with, persons or institutions which do not plainly reveal themselves and their work in the daylight. A general public is always big hearted, and is always highly appreciative of courage and sincerity, but wants to be told all about things, and is not interested in hermits, or in institutions in back streets with closed doors, and hermetically sealed museums. Probably the greatest opportunity we ever had occurred during the late war.

We had the most emphatic lead given to us. The French Army, quite early in the war, engaged a large number of well known artists, and as a result the republic now possesses an enormous collection of invaluable drawings and paintings dealing with every phase of Army life in war time. So far as our own, and medical services are concerned these may be divided into three sections.

1. Pathological and surgical drawings and paintings.
2. Paintings and drawings illustrative of work in the field, in hospitals and transport,
3. Portraits of distinguished officers and men.

I quote the French Army because it certainly has the largest collection of the kind in the world; but the same thing has been done more or less by all the civilised (and some of the uncivilised) armies engaged.

In our own Army the R.A.M.C., more than three years ago, commenced the same kind of work. The result is that although they do not possess the number of works owned by the medical department of the French Army, they have a large number of very fine ones. I have personally examined many of them, and we have certainly never before had anything like them in this country in point of merit or scientific importance.

Also, in our own Army, official artists were engaged who have profusely illustrated the work of apparently every branch of the service except our own. Many of these have already been exhibited to the public at special shows. A large number of these pictures will be preserved in the Imperial War Museum, and will be for all time of great historic value and interest.

One may well ask What have we done in this important matter? How shall we be represented in the Imperial War Museum? And what pathological and surgical drawings and paintings have we to compare in any way with those of the R.A.M.C.

I think I am correct in stating that in this instance we fully acted up to our ancient traditions by doing nothing whatever. So our most recent and priceless opportunity for propaganda goes to join the ghosts of our many other lost chances.

So our pathological and surgical progress receives no kind of emphasis in accordance with modern methods, either with the public or ourselves.

The only pictorial records of the innumerable interesting conditions obtaining during the war, probably consist of a few amateur drawings privately owned.

It is now a matter of common knowledge that the most impressive of all propaganda work is done by means of pictures. Both the educated and the uneducated find their attention arrested immediately by vigorous and live drawings or paintings. A general understanding of the whole subject is taken in at once, and more or less indelibly fixed on the memory.

Written or verbal descriptions of our work are also indispensable, but they can never impress the public mind in the same degree as a vivid pictorial representation of that work actually taking place does. Further, written or verbal descriptions can only reach a very small public, however energetically they may be issued. A picture has the largest public of anything in the world, and appeals (in varying degrees according to their temperament) to all sorts and conditions of men, from the Archbishop of Canterbury to the ragpicker.

We need not have the slightest fear of public opinion, or of over-educating the people (which would indeed be difficult); but accurate knowledge of ourselves and our work is greatly needed in many directions, and it is urgently needed in one direction where it is highly important there should no longer continue to be so great a lack of it, and that is in the House of Commons.

This is not the fault of the House of Commons, it is entirely and absolutely due to our own traditional apathy. Had we been in the habit of allowing the public to know the ordinary, and interesting facts connected with ourselves, our work, our progress and our hopes, we should not only have gained greatly in influence, but we should have no miserably financed colleges, no need of crying to the already much harassed State for help, and no danger of losing that most priceless thing of all—our independence.

HENRY C. WILKIE, F.R.C.V.S., F.Z.S.

#### SALE OF ARMY HORSES: AN EXPERIENCE.

On the 28th of March there was a sale of repatriated army horses at Haywards Heath, the animals having only arrived in this country from France about 14 days previously. Amongst the consignment was a brown mare about 15 hands, a good looking animal in fine condition, not lame, and judging by the mark of harness on the shoulders evidently a good worker. As a client of mine wanted such an animal for his dog-cart he looked her over, and as he could see nothing the matter

with her decided to buy her at the auction sale. He had previously tried to find out from the attendant soldiers and the officer in charge if she was all right, but of course they could give no information as the horses had only been in the country a few days, and had been handed over to them for the purpose of the sale. My client purchased her at the auction for 38 guineas; the only warranty with any of the animals being the freedom from any contagious disease—no guarantee of soundness was given.

Next morning I was requested to see the mare, because after a short distance in the saddle she had bled from the nose. Examining her some little time after her return, I found that the Schneiderian membrane was very much injected, the temperature was 102, the pulse about 52; but the animal did not look ill, and she fed well. Some simple treatment was prescribed and the mare was normal in two days time, whereupon walking exercise for a quarter of an hour twice a day was ordered.

On the eighth day after the sale she was taken out of the stable, walked for 50 yards, then trotted for say a quarter of a mile when she suddenly came to a standstill with blood pouring out of both nostrils, and also the mouth when she coughed; the flanks heaved, the mare was greatly distressed. The blood was bright scarlet, and very profuse for some time. On auscultating the lung there were loud, vibrating rhonchi of various sorts, mostly low-pitched and piping.

The mare is absolutely useless. I cannot recollect meeting with any similar case, and I should be much obliged if anyone who has served over in France will write stating whether the symptoms indicate that the mare has been "gassed."

My client feels very sore about purchasing such a useless, deceptive horse. If the animal had been lame, or had a big leg, or been broken winded, it would have been different, but the fact that the horses came from France indicated that they had been working over there, and as a matter of fact all the rest have, as far as one knows, turned out quite satisfactory. The condition may, or may not have been in evidence in France, but presuming it had been, one would have thought the authorities would hardly have sanctioned the transportation to this country for the purpose of selling.

HENRY TAYLOR.

Haywards Heath, April 7.

---

#### MIDLAND COUNTIES VETERINARY MEDICAL ASSOCIATION. [NATIONAL V.M.A.—NORTHERN BRANCH.]

---

The annual meeting was held at the Grand Hotel, Birmingham, on Friday, Feb. 28th. The president Mr. John Malcolm, of Birmingham, was absent on account of indisposition, and Mr. J. Martin, Wellington, the senior vice-president, took the chair in his stead. There were also present: Messrs T. H. L. Duckworth, Ashbourne; J. J. Burchall, Loughborough; T. Chambers, Dudley; W. H. Brooke, Handsworth; F. L. Gooch, Stamford; R. C. Trigger, Newcastle-under-

Lyne; J. Young, Birmingham; J. Cormack, Coventry; F. O. Powley, Sutton Coldfield; W. E. Ison, Atherstone; J. W. Conchie, Kidderminster; and the Hon. Sec. Mr. H. J. Dawes, West Bromwich.

Apologies for non-attendance were announced from Prof. Dewar, Messrs F. B. O. Taylor, T. J. Brain, W. Trigger, C. S. Hunting, W. Tart, J. R. A. Jones, R. Cockburn, L. W. Heelis, H. L. Pemberton, A. B. Forsyth, W. Grasby, H. S. Reynolds, H. B. Hiles, T. Ludlow, S. J. Marriott, R. Hughes, J. R. Carless, and J. Deville, and others.

The President wrote:

"I regret I cannot be at the meeting today, as the doctor forbids. Since our last meeting, our society has lost one of its pillars by the decease of Mr. W. Stanley Carless, of Worcester. He had taken a prominent part in the Society in connection with matters bearing on the well-being of the profession for the last 35 years. He was in many senses the ideal clinical veterinarian. I personally had come in contact with him in matters quite apart from our Society transactions, and found him a thorough gentleman and true friend. I have had a good few business transactions with him, in some of which he was acting on his own account and others on the account of clients, but it was characteristic of the man that in these transactions he was always keener on behalf of his clients than for himself. I regret we have lost another member bearing a well known name, I refer to Mr. James Blakeway, junior, of Stourbridge, for whose relatives one and all must deeply feel.

The meeting today will, of course, elect the officers for the coming year. We had all hoped that our absent members would have returned in such forces that new officers would have been elected, but seeing many are still absent it may be deemed advisable to continue the present lines for another year. I should like to say that I shall be very pleased to fall in line with whatever is decided upon by the meeting, and am prepared to continue to do the best I can for the Society in any circumstances."

On the motion of the Hon. Sec., seconded by Mr. Gooch, a message of sympathy was ordered to be sent to Mr. Malcolm in his illness, with an expression of the hope that he might speedily be restored to his accustomed health.

#### VOTES OF CONDOLENCE.

The Hon. Sec. said it was his melancholy duty to report the deaths of two very old and esteemed members of the Association in the persons of Mr. Stanley Carless of Worcester, and Mr. James Blakeway, junior, Stourbridge. He proposed that letters of condolence be sent in the name of the Association to their relatives. Mr. Carless was one of their oldest members, who acted as Hon. Sec. many years ago and later had filled the presidential chair. He continued to attend the meetings regularly and would be very much missed by those who had learned to admire him for his professional ability and his personal charm.

In the case of Mr. Blakeway, jun., there was a special note of sadness. He came safely through the war, then he was taken suddenly away. His brother, Dr. Harry Blakeway, of Harley St., London, died a few weeks ago, and the double blow to their esteemed father would cause their hearts to go out to him in special measure. He believed this was the first time in the long history of this Association that the name of Blakeway did not appear in the list of members.

Mr. TRIGGER, in seconding, spoke very feelingly of his old friend Mr. Carless. He said he did not know Mr. James Blakeway, jun., so well, but he remembered his grandfather as one of the founders and earliest officials of this Association, and also his father and uncle. He was quite sure the profession was infinitely the poorer by the loss of two such distinguished men.

Mr. Chambers, Mr. Burchnall, and Mr. Gooch also added personal tributes, and the resolution was carried *sub silentio*.

*New Members.* The following gentlemen, nominated at the previous meeting, were unanimously elected members of the Association:

Mr. C. S. HUNTING, Loughborough, proposed by Mr. Cormack and seconded by the Hon. Sec.; and

Mr. J. R. A. JONES, Gloucester, proposed by Mr. Cormack and seconded by Mr. Brooke.

#### TO HELP OUR ALLIES.

Mr. TRIGGER, in accordance with notice duly given, moved, "That a further sum of £10 be given to the Anglo-Franco-Belgian Veterinary Relief Fund." He said he was sure it would appeal to every member of the profession, who can form but an inadequate conception of what their brethren in France and Belgium have suffered by the war. They were left absolutely penniless. Up to the present about £400 had been forwarded, but from the profession in this country, numbering something like 3000 members, he thought at least £1000 ought to be raised.

The Hon. Sec. seconded. He said the Association voted ten guineas two years ago and he was pleased to think that the state of their exchequer would warrant this further assistance. (The motion was carried *unanimously*.)

#### TREASURER'S ANNUAL STATEMENT.

The Hon. Treasurer (Mr. BURCHNALL) submitted his statement of accounts for the past year, duly audited. This showed members' subscriptions £30-10-0, interest on War Stock, £5, and bank interest £1-14-6. This, with a sum of £93-8-8 brought forward from the previous year, brought the assets up to £130-13-2, exclusive of the capital sum of £100 invested in War Stock. The items of expenditure were as follows: Annual subscription to Victoria Veterinary Benevolent Fund, £5 5 0; Affiliation fee to National Veterinary Association, £3-19-0; special donation to Victoria Veterinary Benevolent Fund, £10-10-0; donation to Army Veterinary Corps Comforts Fund, £7-7-0; secretary's expenses, £25-7-0; Treasurer's expenses £1-2-3; cheque book 2/-; making a total of £53-12-3, and leaving a sum of £77-0-11 to carry forward, or a deficit on the year's working of £16-7-9. This, Mr. Burchnall explained, was due partly to the special donations which would not necessarily recur, and to the fact that many members serving with the colours were temporarily excused payment of their subscriptions. The present membership was 92, compared with 105 a few years ago.

He asked to be excused from further service as treasurer, as his health was not as good as he could wish. He had filled the office for eleven years, and had taken the keenest pleasure in the work.

Mr. ISON, in moving that the balance sheet be adopted, said the Association was in a very sound financial position, notwithstanding the deficit on the year, which had been satisfactorily explained.

Mr. CHAMBERS seconded the motion, which was carried unanimously.

#### REPORT OF COUNCIL.

The Hon. Sec. presented the following report of the Council of the Association, held immediately prior to the general meeting:—

It is recommended (1), that the next meeting of the Association be held in Birmingham; (2), that the matter of a subject for discussion be left to the Hon. Sec. and President to arrange; and (3), that the officers of the Association be re-elected *en bloc* until such time as conditions are more settled than they are at present, except that Mr. F. L. Gooch be elected an auditor in succession to the late Mr. W. S. Carless.

A letter was read from Mr. Burchnall tendering his resignation as Hon. Treasurer, and it is suggested that Mr. W. H. Brooke be approached with a view to his filling the vacancy.

The question of income tax claimed by the Inland Revenue from the Association was adjourned until the next meeting, certain enquiries to be made in the meantime.

A letter was read from Mr. J. Hill, of Llanelly, inviting support of his candidature for the Council of the Royal College of Veterinary Surgeons, and it was resolved that he not being a member of this Association, his candidature cannot be officially endorsed.

A letter was read from the Derbyshire Veterinary Association re Insurance Companies' fees and other matters, and as Mr. Duckworth, representing Derbyshire, was attending the general meeting, it was resolved to await a statement from that gentleman.

Arising out of this report, Mr. Trigger said it would be a matter of general regret that Mr. Burchnall felt it incumbent upon himself to retire from the Treasurership, which he had held with so much credit for the past eleven years. He moved that his resignation be received with regret and that Mr. Burchnall be very warmly thanked for his past services.

This was seconded by the Hon. Sec., supported by Mr. Chambers, and carried unanimously.

The Hon. Sec. next moved that Mr. Brooke be elected to succeed Mr. Burchnall as Treasurer. Mr. Brooke, he said, would make an ideal treasurer, being thorough in all that he undertook.

Mr. Gooch seconded this motion, which was carried unanimously.

Mr. Brooke, in accepting the appointment, said he should rely very much on the assistance of the Hon. Sec. in the discharge of his new duties.

The election of the other officers, with the substitution of Mr. Gooch for the late Mr. Carless as an auditor, as recommended by the Council, was then agreed to *pro forma*, and on the motion of Mr. O'Neill, seconded by Mr. Young, a vote of thanks was passed to them for their promotion of the Association's welfare during the past twelve months.

The report of the Council was then adopted *in toto*, on the motion of Mr. O'Neill, seconded by Mr. Conchie.

#### INSURANCE COMPANIES' FEES.

Mr. DUCKWORTH said the veterinary surgeons of Derbyshire and the immediate neighbourhood had recently formed an Association to further their professional interests, and two meetings which had already been held had been well attended. One thing they had done, was to fix on a scale of fees among themselves and it was working very well, and now they were trying to agree on a uniform charge to insurance companies for the examination of animals. They thought it was high time that veterinary surgeons revolted against the ridiculously low fees that were allowed by some companies, but recognised that any action, to be effective, must have the united support of the profession as a whole. The Derbyshire Society had written to all insurance companies stating that their members would not undertake any examination at a less fee than 10/6 for each animal. That fee was to include mileage, it being understood that they did not make a special journey, but visited the case when next they happened to be in the district.

Mr. Gooch, whilst agreeing with the Derbyshire Society, and endorsing every word that had been said about the inadequacy of the fees that were sometimes offered, thought a hard and fast rule would hardly do. A horse, the property of a poor client, might be insured for only £12, and another for £1000. Were they to hold out for a 10/6 fee in those two extreme cases?

Mr. DUCKWORTH said if the premium would not stand

a 10/6 fee, the insurance company could accept the animal without an examination. As for the examination of very valuable animals, it was not intended that the 10/6 should be other than a minimum fee.

The Hon. Sec. said he should like to thank Mr. Duckworth and the Derbyshire Society for bringing this matter forward. It had been argued that veterinary surgeons accepted a small fee because they were generally dealing with their own clients, but he thought that was not a good excuse. He quite agreed that the time had come when they should make a stand, but it was only by unity that they would get their professional due in this matter.

Mr. O'NEILL suggested that the fee might be regulated according to the amount of the policy of insurance, but he certainly was of opinion that half-a-guinea was the smallest that a professional man should accept. He could speak freely on the subject, because he was outside such a controversy. Was not this a subject which the National Veterinary Society might usefully take up?

Mr. ISON said he had no desire to justify the small fee that was paid in many cases, but it was only a very cursory examination that they were expected to make, and they never made a special journey. He agreed that some small premiums would not stand a 10/6 fee.

Mr. CONCHIE said he made it a rule not to make an examination under 5/- for each animal, plus mileage. He noticed that the medical profession were forming themselves into a trade union for the furtherance of their interests, and he thought veterinary surgeons might profitably follow that example. Other professions and callings could force the hands of the Government by unity of action. Why should not veterinary surgeons, who were a very numerous body, be able to do likewise? If they did not look after themselves, they would be left behind in the great work of national re-construction that was now going on.

Mr. TRIGGER, whilst agreeing in principle with Mr. Duckworth, thought there was something to be said, as Mr. Gooch had suggested, for the poor and struggling client. For a horse belonging to a *bona fide* working-man he thought a fee of 5/- might be accepted, for they all knew that the cost, in the long run, was not borne by the companies but by the owners.

The ACTING PRESIDENT said this was a question which bristled with difficulties. Personally, he took an individual case on its merits, and if it was not worth his while to undertake it, he did not do so. The increased value of stock must mean a considerable increase in the revenue of the insurance companies, and he was willing to support any reasonable proposition that might be put forward. He thought it should be on a percentage basis.

The Hon. Sec. said he was strongly in favour of supporting the action of the Derbyshire Society in endeavouring to establish a minimum fee of 10/6 for the examination of animals for insurance. He thought it would be a good subject for the agenda for the next meeting. He moved that it be brought forward then, and that in the meantime members be asked to hold out for a 10/6 fee.

This was seconded by Mr. Chambers and carried unanimously.

#### PETROL FOR VETERINARY SURGEONS.

Mr. DUCKWORTH said that another matter which the Derbyshire Society had discussed was the cost of petrol, and they had decided to approach the proper authorities with a view to veterinary surgeons being accorded the same favoured treatment as traders.

It was resolved that this question also be raised at the next meeting.

#### VETERINARY POLITICS.

The Hon. Sec. mentioned the Ministry of Health Bill, and a discussion took place in regard to same.

Mr. POWLEY said if they did not take action at once, it would be too late. He urged that veterinary surgeons should do as the medical profession was doing—form some sort of trade union to push their claims for proper recognition. He should have thought the National Association would be up and doing before this.

The Hon. SEC. said it was clearly a matter for National effort: if left to individual Associations, too much valuable time would be lost, as the Associations only met at considerable intervals.

Eventually, on the proposition of Mr. Powley, seconded by Mr. Duckworth, it was decided to form a small Sub-Committee with power to act.

It was further resolved, that the Committee should consist of the following:—The President, the Hon. Sec., Mr. Brooke and Mr. Chambers.

#### COUNCIL OF R.C.V.S.

Mr. R. C. TRIGGER said that Mr. Dawes had brought forward the question of the new Ministry of Health Bill and the necessity of carefully watching the interests of the profession by the Council. He (Mr. Trigger) said this was a new Bill and the draft not yet before them; but it was certain that it would have the careful attention of Council. Further, they might rely on Mr. Thatcher and Mr. Bullock to carefully note and report anything adverse to our interests. He further said that he would like to take the opportunity of saying a few words in relation to matters affecting the interests of the profession and the attitude of Council thereon. He said that whilst welcoming criticism and a more lively interest in the work of the Council, there had been a certain amount of criticism (not too kindly) of the work of that body, due, he thought, very largely to want of knowledge of facts, and he entirely failed to find any kind of constructive criticism—simply destructive. The chief subjects of complaint seemed to be—first: Teachers as members of the Council, and suggestions that they should be barred from office. This matter was entirely in the hands of the profession, as it was by their votes that teachers were returned. For himself he was, after a long experience, satisfied that their presence and suggestions are at times absolutely necessary; for unless some subjects were fully and fairly agreed before Council, a state of confusion or chaos might arise, between the Council and the Schools. At the same time whilst holding these views, he also thought that the Schools were over-represented. His present view was that one only should be allowed for each teaching school, and that when one school was already represented, no other teacher from that school should be eligible for nomination. As before said, the profession had the control of this matter entirely in their own hands.

The next criticism usually was on work of Registration Committee, and the putting down of quackery. The Council have no power at all to deal with quackery as such in this connection: they can only deal with men who in some way represent themselves as qualified to practise.

In other particulars, Council has been terribly handicapped for want of funds. For years now we have had to struggle on with very inadequate, or in fact practically no means. Prosecutions taken up by this Committee prove very expensive work, entailing as they do employment of solicitors in various parts of the Kingdom. Even when convictions are obtained (as they usually are) and costs allowed, such costs do not nearly repay amounts incurred. In this connection it may be mentioned that one case that went to appeal, though eventually given in our favour, appeal being dismissed, cost us round about £100. During the last few years we have had Public Health Bills watched by special committees; Army schemes watched and more satis-

factory conditions obtained; Milk and Dairy Bills amendments introduced, milk clauses opposed and finally struck out; later Milk and Dairies Bills, again amendments secured; Petitions re Motor and Petrol tax rebates eventually secured. Motor car licenses, rebate obtained; Petrol rebates as medical men, and here we are deeply indebted to Mr. Bullock, our most able secretary, for assistance in remedying grievances and obtaining supplies of rectified spirit at reduced rates; Coal Mines Bill, deputation to Home Office, V.S. to test for glanders. Some of these and the Milk and Dairies Consolidations Act involved lobbying, and of course thereby additional expenses. You have a scheme for provision of State Scholarships for veterinary students, first proposed by Council in 1918, now approved by Government for students generally; our profession has its representative on each of the twelve district advisory committees for selection of students for these grants. I do not think the Council can fairly be accused of being asleep. On the other hand I do think there is cause for complaint of the apathy of the profession—less than one third of the members subscribe to the College, and the subscribers are not the men who are grumbling. I can assure you that the vigilance of Registration Committee has been partly wasted for lack of funds. The Finance Committee's worries and anxieties are perhaps hardly realised; and only those who are on the Council can realise the enormous amount of time taken by Examination Committee and its frequent meetings.

All honour to those men who have subscribed and staved off disaster and kept the ship afloat through these last terrible years, until at last we can begin to hope that we may soon see a ray of light. Our Annual Fee Bill like many other non-Government Bills has been hung up, although re-introduced each year during the war. It is for the veterinary profession to use whenever possible influence with members of Parliament to secure support, as there will be an earnest renewed endeavour to get the Bill through this Session.

The Acting President proposed that the best thanks of the meeting be accorded to Mr. Trigger for his very interesting remarks. This was seconded by the Hon. Sec. and carried unanimously.

#### INTERESTING CASES.

Mr. O'NEILL produced the first dorsal vertebra of a van horse, which was fractured as the result of an accident. The animal was in a pair-horse-van and the other horse ran away taking this one with it. The horse that bolted escaped injury, but this one ran its head into a wall. It seemed dazed, and he thought it was suffering from concussion. It was got on to its feet, and he thought it would come round, but it died shortly afterwards. The surprising thing was that the fracture should have taken place so far down.

The Hon. SEC. produced a long piece of wire taken from the body of a fox terrier puppy, eight weeks old. It was part of a hat pin and was nearly as long as the puppy itself. It was extracted by an operation which involved an incision in the chest. The opinion of the members was that the puppy had swallowed the hat pin knob first, and that in the process of extraction the knob had come off and been left in the body. The puppy, a valuable one, had made a complete recovery.

Mr. YOUNG showed a bad case of fractured tibia. The bad feature of this case was that before he was called in, the animal was treated by a man demobilised from the Army Veterinary Corps who professed to understand these things. The man had treated the patient, a valuable cart-horse, for abscess on the thigh, and he considered it a case of such gross cruelty that some action ought to be taken to prevent such a thing happening again.

F. L. GOOCH said: I was summoned to a farm at 11.30 p.m. to a Lincoln red shorthorn heifer unable to calve. Upon examination I found presented the internal viscera of the calf: all the abdominal and thoracic viscera were placed outside the body of the foetus. I removed all the viscera and found that the calf was doubled on itself, with all the limbs and head turned back in the uterus. I was just able to feel one hock, but found that every joint was stiff, and the only method for removal was to cut the foetus in halves. The heifer was worth nearly as much for beef as for a breeding animal, and I explained to the owner that it would be a difficult operation and might injure the heifer, and advised slaughter, which he readily agreed to. After slaughter the uterus was removed entire, and the foetus removed and photographed.

Mr. CONCHIE showed a long piece of wire taken from the right ventricle of the heart of a cow, which before death presented all the appearance of a case of blind staggers.

Mr. CHAMBERS exhibited a large tumour, weighing 2lb, which the butcher found on the left ventricle of a cow's heart. A vote

of thanks was accorded to these members.

H. J. DAWES, Hon. Sec.

#### MINISTRY OF HEALTH BILL.

A meeting of the Committee appointed at the annual meeting of the Midland Counties Veterinary Medical Association in connection with the above matter, was held at Mr. Malcolm's office, Holliday Street Wharf, Birmingham, on Friday, March 7th, 1919, at 6 p.m.

Present—Mr. J. Malcolm in the chair; Messrs. J. O. Powley, W. H. Brooke, and H. J. Dawes. An apology was received from Mr. T. Chambers, Dudley. After considerable discussion it was resolved to send a copy of the following resolution to the Council of the Royal College of Veterinary Surgeons:—

"That this Committee is of opinion that the attention of the profession should be called to the Ministry of Health Bill now before Parliament—as tremendous issues appear to be involved, and apathy and inaction at the present juncture will seriously injure the future of the profession.

This Committee beg to suggest to the Council of R.C.V.S. that a strong representative Committee be formed to look after the interests of the profession in the passage of the Bill through Parliament—the Committee to consist of members of the Council of R.C.V.S. with any co-opted members thought desirable. The matter is urgent, and this Committee suggest that it be dealt with by a special meeting of Council.

#### LANCASHIRE VETERINARY MEDICAL ASSOCIATION (NATIONAL V.M.A.—NORTHERN BRANCH).

The combined Annual and General meeting was held at the Grand Hotel, Manchester, on Thursday March 6th. In the absence of the President, Mr. G. H. Locke, Mr. W. Woods, Wigan, was elected to preside. The attendance included Messrs Lawson, Hopkin, Carter, Hewetson, Sumner, Blakemore, Curbishley, Lieut. Col. J. W. Brittlebank, C.M.G., and Capt. E. H. Stent.

Apologies for absence were received from Messrs Darwell, Clarkson, Wharam, Wolstenholme, Abson, and Packman.

The consideration of the minutes of the last meeting was deferred.

Col. BRITTLEBANK proposed that a vote of condolence be forwarded to Mrs. Holburn, expressing their extreme regret at the sad loss she has sustained by the death of her husband. Mr. Holburn was an old friend and highly respected member of the Association, and wherever he went was always welcome and helpful in any proceedings that concerned the profession.

Mr. CURBISHLEY in seconding the proposal said that Mr. Holburn had been his nearest neighbour, and the district was a loser by his death. The resolution was passed in silence.

*Election of Officers.* Mr. Sumner proposed that the officers and Council be re-elected *en bloc*, except that the name of Mr. Hewetson be substituted for that of Mr. Holburn. Mr. Carter, seconded.

The names are as follows—*President* Mr. G. H. Locke *Vice-Presidents* Mr. W. Ackroyd, Mr. A. Noel-Pillers, Mr. J. H. Wright and Mr. H. G. Hewetson.

*Hon. Treasurer* Capt. E. H. Stent, *Hon. Sec. Lieut.* Col. J. W. Brittlebank. *Auditors* Mr. W. A. Taylor and Mr. J. Ingham. *Council.* The above officers together with Messrs J. Clarkson, T. Hopkin, A. Lawson, J. McKinna, A. Munro senr., W. Packman, H. Sumner, J. B. Wolstenholme and W. Woods.

*Treasurer's Report.* Capt. Stent stated he had no detailed statement to bring forward. There was about £22 in the bank. He submitted a list of members whose subscriptions are in arrear, and asked that consideration be given to the question of cancelling one or two years. There are about eighty-nine members on the books.

Mr. Woods pointed out that only one meeting had been held since the year 1914, and consequently no advantage accrued by being a member of the Association. He suggested that the subscriptions for 1915, 1916 and 1917 be not asked for.

Col. BRITTLEBANK agreed with the suggestion, and said every effort should be made to keep their members together. He thought there might be a tendency in the future to form numerous small associations, and so dissipate our strength.

Mr. SUMNER proposed that subscriptions for the years 1916, 1917 and 1918 be waived. Col. Brittlebank seconded. Carried.

Mr. SUMNER then proposed that the Executive be empowered to notify the members, to call in arrears prior to 1916 and to ask for subscriptions for the current year.

Mr. CARTER seconded the proposal which was adopted.

*Election of Council R.C.V.S.* Mr. SUMNER thought the time was opportune to nominate their President, Mr. G. H. Locke. He said all would have noticed a feeling of dissatisfaction in the profession regarding the work of the Council. There is, he said, even in the south, a section which is anxious to get on the Council with the intention of infusing new blood and new ideas, in the hope that their influence will make the Council more progressive. He thought this section would be a large one. He did wonder, however, in what respect the Council had fallen short of fulfilling its duties. As a Councillor, he considered it a good sign that the profession is showing more interest. He asked if the Lancashire Association was in a position to associate itself with kindred societies with a view to enhancing the chances of election of their nominees, Mr. A. Lawson and Mr. G. H. Locke. Both are eminently qualified, and he proposed that their nomination be recognised by the Lancashire V.M.A., and that it take every means in its power to secure their election.

Col. BRITTLEBANK, seconding, remarked that the happenings of the past four and half years will be largely responsible for an entirely new phase of ideas in a good many members of the profession. Many had had experiences of life which they had not had before, and the agitation referred to was an excellent sign, although he deprecated some of the expressions used in giving effect to opinions that certain people hold. The Royal College, like every other body during the past four years, has had to carry on its work under considerable difficulties. He was not pleading for himself, but he was perfectly satisfied that so far as it had been possible legitimately to carry on business the Council had done excellent work.

They in the north, would feel themselves honoured to support the two candidates whose names were now before the meeting, and he also wished to say that as an

Association they were entitled to use all legitimate means in their power to secure the successful return of both gentlemen; and he hoped that the Council would be authorised to take such steps as may be necessary, by combination with other associations especially, to see that both Mr. Locke and Mr. Lawson were elected to the Council of the Royal College of Veterinary Surgeons.

The prospects before the profession were, in his opinion, such as required high qualities of statesmanship. Practically every calling required reconstruction. In his opinion, the prospects before the Veterinary profession were excellent only if we are capable of firm determination to direct our energies in the proper direction, and to set before ourselves a high standard for attainment which is not unmindful of the public welfare.

The proposition was carried unanimously.

Mr. LAWSON thanked the members for their promise of support. He had been a member of the Council for twenty years, and had always endeavoured to attend the meetings and further the interests of the profession.

Mr. CURBISHLEY pointed out that one candidate suggests that expenses be paid.

Mr. SUMNER replied that in the present condition of finance this is quite impossible. They did not know what re-construction is going to do, or what the grants are going to be. It is humiliating to think they had to be kept alive by the subscriptions of members.

Mr. HOPKIN thought that the men who are getting up the agitation are the disappointed men.

Col. BRITTLEBANK asked was it not rather a political move, and did they not want to convert the Council into a political society. If they could do so and at the same time maintain it as a governing body, he would be satisfied.

#### PROPOSED PARLIAMENTARY BILL OF THE NATIONAL MASTER FARRIERS' ASSOCIATION.

The following extract from *The Farriers' Journal* for January, 1919, was considered:—

#### INTERIM RECONSTRUCTION COMMITTEE: FARRIERS AND BLACKSMITHS.

#### SCHEME FOR COMPULSORY REGISTRATION OF FARRIERS.

In accordance with the recommendations made in the Whitley Report, the Interim Reconstruction Committee which has been formed in the Farriers' and Blacksmiths' trade, consisting of representatives of the National Master Farriers' Association, the Irish Master Farriers' Association, and the Amalgamated Society of Farriers, hereby memorialise His Majesty's Government on the subject of the better training and registration of farriers.

Whereas during the past century—while almost every trade and industry has been advancing in improved and scientific methods of carrying on its operations—the farriery trade has been practically at a standstill, and although efforts have been made by the Worshipful Company of Farriers of London, the Royal Agricultural Society of England, the Department of Agriculture and Technical Instruction for Ireland, and a few other bodies, to establish a more scientific method of horse-shoeing, yet amongst the great body of the trade there has been no improvement; and

Whereas it is expedient in the National interest that horses should be shod in a scientific manner, because many thousands of horses are so injured by wrong methods of shoeing every year that their working lives are very materially shortened, it is deemed necessary that farriers (or shoeing-smiths) should receive technical instruction in the structure of the horse's foot and the scientific principles of shoeing, and

Whereas there is at present no organised method or means of obtaining this instruction and training, it is the desire of the said Reconstruction Committee that

His Majesty's Government forthwith introduce a Bill making it compulsory that farriers (or shoeing-smiths) shall undergo a course of training and fit themselves to pass an examination, before being allowed to practise the craft, and

Whereas the shoeing of a horse—besides requiring great mechanical skill in the making, fitting and nailing of the shoes—is a surgical operation performed on a living structure, and

Whereas such legislation has been passed in several of the British Colonies and in some of the countries on the Continent of Europe for the purpose of ameliorating the lot of horses and prolonging their working lives, the Farriers' and Blacksmiths' Reconstruction Committee make the following suggestions for the framing of an Act of Parliament for the Compulsory Examination and Registration of Farriers (or Shoeing-smiths):—

- 1 That the said Act shall be framed on the lines of the Veterinary Surgeons' Act, 1881.
- 2 That the Worshipful Company of Farriers of London (a Livery Company of the City of London Guilds, established in 1356 and Incorporated by Charter) shall be the Examination and Registration Authority for Great Britain and Ireland.
- 3 That the Registration Council shall contain among its members an equal number of members of the National and Irish Master Farriers' Association and members of the Amalgamated Society of Farriers, each and all of whom shall also be Registered Farriers by examination of the said Worshipful Company of Farriers.
- 4 That after the passing of this Act no person shall be licensed to practise farriery or engage in business or practice as a farrier (or shoeing-smith) unless he shall have served an apprenticeship of at least five years, and shall pass such examination—theoretically and practically—in the structure of the horse's foot and the principles of shoeing, as may be fixed from time to time by the Registration Council.
- 5 That any person over 30 years of age at the passing of the Act who has continuously practised farriery for not less than ten years, but is not on the Register of Farriers, shall be entitled within three months of the passing of the Act to be placed on a separate register under the heading of "Existing Practitioners," without examination, but shall not be deemed to be a licentiate of the Worshipful Company of Farriers.
- 6 That after the passing of the Act no person who is not licensed or registered by the Worshipful Company of Farriers shall use any name title, addition, or description by means of initials or letters placed after his name, or otherwise stating or implying that he is licensed or registered by the Worshipful Company of Farriers, or that he is a person specially qualified to practise as a farrier or shoeing-smith (under a penalty).
- 7 That it shall be incumbent upon all Technical Education Authorities throughout Great Britain and Ireland to supply facilities and instructors for the giving of lectures and demonstrations in the art of farriery at fair and reasonable fees.
- 8 That the said instructors, before being appointed, shall pass a special examination by the Board of Examiners of the Worshipful Company of Farriers.
- 9 That similar provisions, penalties, etc., as are included in the Veterinary Surgeons Act, 1881, 44 and 45 Vict., Chapter 62, shall also be embodied in the Farriers (or Shoeing-smiths) Act in so far as Clauses 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 17, 18, and 19.

It may be pointed out that, in the interests of the horse-owning public, it is urgently necessary that some legislation should be passed without delay, as there is a very grave risk of the country being flooded with a large number of semi-skilled men when demobilisation takes place, who, if allowed to practice farriery without

restraint, will cause incalculable damage to horses and loss to the owners."

Mr. SUMNER thought nothing could be done until the bill was presented.

Mr. CARTER proposed that copy of the paper be sent to The Royal College, and to *The Veterinary Record* and *Veterinary News*. Mr. Hopkins seconded.

Col. BRITTLERANK was of opinion that they should go further. They should elect a small committee of gentlemen interested in this matter to watch the proceedings and bring forward a report. The report should not be confined to local consideration. They should then take steps to call a meeting of the Northern Division of the National V.A. At the same time they could set machinery in motion to see that every division considers the same thing. The whole of the resolutions of the Associations to be considered by the N. V. A.

In the period of reconstruction it will behove the profession to watch its interests closely, and legislation would have to be very carefully scrutinised, and he hoped that the profession would become firmly united to secure their position. Mr. Curbishley seconded.

The Sub-Committee appointed consists of Messrs Hopkin, Lawson, Sumner, Blakemore, Taylor, Capt. Stent, Locke, and Wolstenholme; with power to add. Capt. Stent to act as Convener *pro tem*.

*Abscesses after Injections.* Capt Stent brought up the question of abscess formation at the point of injection, which was generally considered as being due to needle or skin infection. He stated that it was not necessarily so, as from experience and laboratory cultivation the infection was frequently due to vaccines or sera being non-sterile, and suggested that if any number of abscesses were met with, the material used should be tested at a laboratory.

A meeting of the Special Committee of Lancashire V.M.A. was held in Manchester, on March 13th, for consideration of the Master Farrier's Parliamentary Bill. Present—Mr. G. H. Locke in the chair, W. A. Taylor, H. Sumner, H. Blakemore, J. B. Wolstenholme, T. Hopkin and Capt. E. H. Stent, Hon. Sec., *pro tem*.

After due consideration the following resolution was adopted:—"That in view of the interference with the rights of veterinary surgeons to conduct the business of shoeing-smiths now threatened by the proposed Bill of the National Master Farrier's Association, every means be taken to oppose the passing of the Bill so far as it effects such rights."

#### VETERINARY POLITICS.

Sir,—“Dagonet” finds fault with certain of our members for airing their grievances but suggesting no remedies. What remedies does he himself suggest; or what attitude except that of ass-like patience and submission? The gem of wisdom that he points to in “Fra Diavolo’s” letter is a mere recommendation to make ourselves a band of sycophants or nonentities. Years ago Gilbert made a list of people who “never would be missed” and could be done without, but he didn’t include veterinary surgeons. Anybody can make out quite a lot of people that could be dispensed with if we all lived the simple life, e.g., insurance agents, plumbers, tailors, costumiers, soap manufacturers, tram conductors, miners, railwaymen, cotton-spinners; but thank God civilisation has advanced too far ever to make it likely. History has proved that it is bodies of men who have kept their claims to the fore, and been good demanders and propagandists that have advanced. It is the dissatisfied beggars that have got on. It is no good clinging to ruins or to huckstering finance. If insurance companies did do without us, would it be any great loss at 2/6 or 3/6 a time?—Yours faithfully,

G. MAYALL, M.R.C.V.S.

## AN ENQUIRY.

Sir,—I enclose memorandum of two Existing Practitioners, evidently brothers, with what appears to me to be a new qualification, R.P.V.S. Can any member tell me through our valuable Record what is the meaning of these letters? Is it a new qualification granted to them?

M.R.C.V.S.

[This communication is anonymous. Both the names are on Register III, R.C.V.S., and have been for at least 30 years, and at the same place. The fragment of heading enclosed bears no date, and like another document used in a similar manner, may be years old.]

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919:—

Duncan, A. C., Major R.A.V.C.	£1	1	0
Edmondson, W., Harrogate	1	1	0
Elmes, G., St. Albans	1	1	0
Freeman, R. B., Dublin	1	1	0
McCunn, J., Lieut. R.A.V.C.	1	1	0
McKerlie, J., Hungerford	1	1	0
Mayall, G., Bolton	1	1	0
Towne, A. H., London, N. 16.	1	1	0
Previously acknowledged	£697	17	0

April 9. £706 5 0

ANGLO FRANCO-BELGIAN VETERINARY RELIEF FUND.  
10 Red Lion Square, W.C. 1.

The following Donations are gratefully acknowledged:—

W. Anderson, Keith	£1	1	0
E. J. Burndred, Major R.A.V.C.	2	2	0
W. Edmondson, Harrogate	1	1	0
G. Elmes, St. Albans	1	1	0
D. C. Greene, Capt. R.A.V.C.	1	1	0
W. T. Oliver, Capt. Tamworth	1	1	0
F. C. Scott, Capt. R.A.V.C.	1	1	0
H. L. Torrance, Capt. R.A.V.C.	1	1	0
A. Weighton, Hull	2	2	0
Previously acknowledged	122	8	6

April 9. £133 19 6

## ARMY VETERINARY SERVICE

Buckingham Palace, Mar. 20.

His Majesty held an Investiture in the Ball Room of the Palace at 11 o'clock.

The following were severally introduced into the presence of The King, when His Majesty invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted:—

## THE DISTINGUISHED SERVICE ORDER.

Major JOHN STEVENSON.

April 5.

Major LOUIS MCKENZIE, Australian A.V.C.

Mar. 27

Major WILLIAM KENNEDY, East African V.C.

Mar. 22.

O.B.E. (Military Division).

Major REGINALD HORE, Australian A.V.C.

Mar. 29.

## THE MILITARY CROSS.

Captain JOHN DAVIDSON, Australian A.V.C.

War Office, Mar. 15.

The names of the following have been brought to the notice of the Secretary of State for War for valuable services rendered during the war in Military Record Offices in the United Kingdom, and, when applicable, an entry will be made in the records of service of officers and other ranks:—

Major (A/Lt.-Col.) R. C. COCHRANE, F.R.C.V.S.

Mar. 25.

The names of the following have been brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the war, and when applicable an entry will be made in the records of service of officers and other ranks:—

T/Capt. T. BOWHILL.

Mar. 27.

T. Capt R. J. COLLINGS; Major J. A. CONNELL; Capt. W. A. MACGREGOR; T/Capt. J. PURDY; Capt. A. G. SAUNDERS, (T.F.); T. Maj. (A. Col.) R. J. STORDY, D.S.O.; Capt. (T/Maj.) J. TAGG, (T.F.); Capt. G. W. WEIR, (T.F.); Maj. A. WILSON, F.R.C.V.S., Unattd. List (T.F.).

War Office, April 5.

The following are among the decorations and medals awarded for distinguished services. The King has given unrestricted permission in all cases to wear the decorations and medals in question:—

Conferred by the King of the Belgians.

## CROIX DE GUERRE.

Capt. R. C. MATTHEW, Canadian A.V.C., attd. 9th Brig. Can. F.A.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Mar. 21.

## REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

The follg. temp. Capts. relinquish their comms. (March 22), and retain the rank of Capt.:—V. Franklin, on acct. of ill-health; C. E. Huston, on acct. of ill-health contracted on active service.

Mar. 28.

Temp. Capt. J. Conner relinquishes comms. on account of ill-health contracted on active service (March 20), and retains rank of Capt.

Mar. 29.

Temp. Qrmr. and Lt. A. H. Webber to be Capt under Art. 330, R.Wt. for Pay and Promotion (Feb. 15).

April 4.

Capt. and Bt. Maj. (temp. Lt.-Col.) E. E. Bennett, ret., reverts to unemployment (Jan. 24), and retains the rank of Lt.-Col.

The follg. relinquish their comms. (April 5):—Temp. Capt. J. P. Dunphy, on acct. of ill-health, and retains the rank of Capt.; Temp. Hon. Lt. C. Young, on acct. of ill-health contracted on active service, and retains the hon. rank of Lt.

April 5.

Maj. (temp. Lt.-Col.) F. S. H. Baldrey, C.M.G., ret. pay, reverts to unemployment (Mar. 5) and retains the rank of Lt.-Col.

April 7.

Can. A.V.C.—Temp. Lt. A. Macintosh is dismissed the Service by sentence of a General Court-martial (Mar. 25).

April 8.

Temp. Capt. W. McQuiston resigns his commn. (Apr. 9), and retains the rank of Capt.

April 10.

Temp. Qrmr. and Lieut. C. G. Kimber, R.A.V.C., to be Capt. under Art. 330 R. Wt. for pay and promotion (April 1).

TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

Mar. 21

Capt. Q. A. Stewart relinquishes his commn. on account of ill-health contracted on active service (March 21), and retains rank of Capt.

Mar. 22.

Capt. C. Baxter be to Maj. (Feb. 28).

April 1.

Capt. G. M. Davey to be Maj. (March 23).

April 3.

Capt. F. E. Jones relinquishes his commn. on account of ill-health (April 4), and retains the rank of Capt.

Amendments to supplement to "*London Gazette*"  
Dated January 1st.

For Maj. and Bt. Lt.-Col. John James Aitkin, D.S.O.,  
read Maj. and Bt. Lt.-Col. John James Aitken D.S.O.

### Failing to Notify Mange.

At Woodbridge Sessions on Thursday, 3rd inst, William Turtill, M.R.C.V.S., Wickham Market, was charged with failing to report the disease of a horse on March 27th.

Miss Cobbold, of Sutton Haugh, stated she called in defendant to look at a horse, and in consequence of receiving a letter requested him to destroy the animal, which was done.

Mr. Horace L. Roberts, F.R.C.V.S., Ipswich, deposed to examining some horses, which he found were suffering from a disease.

In the course of the case it transpired that defendant had been an Inspector under the Animal Diseases Act for over 20 years, and no complaint whatever had previously been made against him.

Defendant said he did not meet Miss Cobbold when he visited Sutton Haugh. The horses were verminous, through being on marshes at Shingle Street. He prepared a lotion, and hoped it would disperse the complaint. During the last few years a great number of duties had devolved upon him, and he had been doing three men's work. At a later date he saw the horses, when they were in a very bad condition. He had previously examined them on two occasions, but failed to detect mange. Subsequently he advised Miss Cobbold to report, or kill the horses. Great difficulty was experienced by veterinary surgeons in separating verminous condition from mange. He was under the impression that after reporting the matter to the owner it was not imperative for him to report the disease, but for the owner to do so.

The Chairman said the Magistrates felt that defendant having been a veterinary inspector for over 20 years, should have known it was his duty to report such a dangerous disease. They ordered him to pay a fine of £3, including costs.—*East Anglian Daily Times*.

### Alleged breach of warranty at Dudley.

At the Dudley County Court on Thursday, before his Honour Judge R. W. Ingham, James Price, haulier, Dudley, claimed £67 14s. 9d. in respect of breach of warranty of a horse which he had purchased from Joseph Turner, farmer, of Kate's Hill. Mr. J. F. Eales appeared for plaintiff, and Mr. W. F. Gandy for the defendant.

Defendant sold a horse to the plaintiff on November 17th. Plaintiff paid £81 for the horse, and alleged that it proved unsound; that when he later sold it at Cave's he only received £35 14s. for it. He claimed £67 14s. 9d., including the keep of the horse for six weeks.

Price, giving evidence, said that defendant verbally warranted the horse as sound and a good worker. He stated that he later found this not to be so, and that the horse fell down while at work. His account was that the horse's neck "came up" and affected his legs, with the result that he fell down in the Himley Road. The horse was afterwards examined by Mr. Chambers, veterinary surgeon, Dudley, who certified it as unsound and unable to move heavy loads.

In cross-examination plaintiff said he did not think the trouble was due to the horse working in fresh harness.

In further cross-examination counsel read an advertisement from the "*Express and Star*"—For sale, dark brown horse, six years, 16 hands, sound wind and eye, good worker in harness.—48, Flood St., Dudley.

Plaintiff admitted that the advertisement was in reference to his horse, but denied that he himself was responsible for the words. He suggested in answer to counsel that the "young lady" who took down the advertisement supplied the words.

Counsel: That advertisement appeared the same day as you received the certificate from Mr. Chambers that the horse was unsound.

Plaintiff: I was told I had better sell him. He was only fit to be killed. I didn't put those words in the paper.

Mr. Thomas Chambers, M.R.C.V.S., said he had known the horse for twelve months. It was brought to his infirmary in July of last year, when it was in the possession of William Lee, of Netherton. The horse had had an injury to the neck and lost the use of its forelegs. On the 19th December, when he examined the horse for the plaintiff, there was an enlargement on the near side of the neck and loss of power in the forelegs. The horse was unsound. He was not surprised to hear that it fell down. Rest and absence of work would help it to grow out of the complaint.

By Mr. Gandy: It was suffering from injury to the spine, which was not incurable.

John Woodall, who claimed a good deal of experience of horses, said that he was present when the horse was purchased, and stated that it was described as sound and a good worker, and had no fault except that it was difficult to shoe.

Albert Price, brother of the plaintiff, also gave evidence on the same subject.

Mr. Abraham Green, M.R.C.V.S., for the defence, said that he had been in practice in Dudley for 50 years, and giving his opinion of the horse's condition when he examined it in January, said that it was suffering from imperfect action in the forelegs and a swelling of the neck, but it was merely a temporary injury probably caused by a collar that was too narrow. The action of the forelegs was quite involuntary, and was caused by the injury to the withers. He had recently had the horse out, when it was perfectly sound, with the exception of the two slight marks on the withers. His conclusion was that Mr. Chambers had made a mistake in his diagnosis.

Cross-examined, he said that if, as Mr. Chambers stated, the bones of the neck were injured, the swelling would not disappear between the times when Mr. Chambers and witness examined it. The horse might certainly improve with two months' rest if the vertebrae were injured, but it would not entirely recover.

Re-examined, Mr. Green stated that the horse had now received treatment, and was perfectly all right.

Mr. Herbert Lloyd Pemberton, M.R.C.V.S., Bridgnorth, said he had examined the horse on Monday, and found it perfectly sound, with the exception of two marks on the withers and a very slight tenderness on the near side. There were no signs of enlarged vertebrae. He had seen the horse draw a cart loaded with a ton of mangolds out of a heavy field and down a steep hill in a perfectly sound manner. If the horse had had the complaint alleged in November, he did not think it would have been able to act in that way.

Cross-examined, witness suggested that if the horse had sore withers in November, the pressure of the collar would cause it to fall. Beyond that he could not suggest any other cause.

The Judge: Do sore withers constitute unsoundness?

Witness: They arouse suspicion.

Re-examined: When a horse changes ownership and gets into new harness, that is when you get the trouble. Badly fitting harness affects the withers.

Turner in the box stated that he acquired the horse in October from Lee at a value of £82. He had no warranty, but had seen the horse at work and knew he was a good worker. While the horse was in his possession he found nothing wrong with it, and was quite

satisfied with it. Referring to the sale of the horse to the plaintiff, he said that he did not offer the horse for sale, but plaintiff and Woodall came and asked if it was to be sold. He denied ever giving any warranty at the time of the sale that the horse was sound and a good worker. The day after Woodall examined the horse thoroughly, the fore legs and the hind legs. The horse was backed and turned, and the only question asked was whether the horse would draw a load of coal. Plaintiff said he was satisfied, he had seen the horse at work, and he paid the money down. Plaintiff did not ask for any receipt or any written warranty. Respecting the part of the claim for the keep of the horse at £2 a week, defendant said he thought that was excessive.

Cross-examined, defendant said the horse was now once more in his possession, and he was quite satisfied with him. He paid a man £1 to buy him at the auction when he was sold for £35 14s.

The Judge: So you have got the horse and £50 as well out of this transaction? Are you going to sell him again?

Lee, the first owner of the horse, from whom defendant had acquired it in October, spoke as to the condition of the horse, and stated that up to the time that he sold him "there was not a better horse in the world for work," and the only reason he parted with him was because he was difficult to shoe.

His Honour said that whether the horse was suffering from an enlargement of the neck or from anything else he had no doubt that it was unsound, and he would give judgment for the plaintiff for £56 14s.—*The Dudley Chronicle*.

VOL. XXXI.

## THE COUNCIL MEETING.

The report of Council meeting is exceedingly long, mainly resulting from the great quantity of work covered in the Committee reports, which form the chief features of the proceedings. While not containing much of acute interest, the whole report deserves study, and should convey at least one useful lesson to not a few members.

The financial position is rather better than usual; but only voluntary subscriptions have made it so. A further appeal for these is to be issued with the Annual Report, and a great deal depends upon how members respond to it.

The amount of work reported upon by the Examination Committee is simply tremendous. Members have only to examine the detailed lists of the numerous applications for exemption, remembering that each case constituted a separate problem for the Committee, to find ample evidence of this. We know that all were considered sympathetically; but the number of applications that were refused shows that sympathy was kept within bounds.

The Parliamentary Committee's work has been little less onerous; and several of its items must be reserved for future notice. An interesting one is that, as was inevitable, the question of admitting women to the profession has been revived, and is to be further considered by the Council. A more important matter, which may affect not a few members whose practices have been closed down through the war, is the Military Service (Civil Liabilities) Regulations.

It has been questioned of late whether the importance of the Ministry of Health Bill was realised at Red Lion Square; but the report reveals much activity with regard to it and the analogous measure for Scotland. In fact, the whole report should open the eyes of those who clamour for the Council to "wake up" in matters affecting the profession. The Council is constantly concerning itself with more of such matters than some of its noisiest critics ever heard of. Most of the decisions are really reached in Committee, and endorsed without comment by the Council; and even men who read the reports carefully can form only a crude idea of the quantity or nature of the work done.

There was one regrettable feature of the meeting—it was too small to act on the Registration Committee's report. It is a pity that this fault, unknown in pre-war days, should have marred a meeting which otherwise fittingly wound up one of the busiest and most useful years of Council work we have ever had.

## Royal College of Veterinary Surgeons.

A Quarterly Meeting of Council was held at 10, Red Lion Square, London, W.C., on Friday afternoon, April 11th. Mr. F. W. Garnett, C.B.E., President, occupied the chair, and the following members were present:—Major J. Abson, D.S.O., Mr. G. A. Banham, Major-General L. J. Blenkinsop, D.S.O., Dr. O. C. Bradley, Lieut.-Colonel J. W. Brittlebank, C.M.G., Messrs. J. Clarkson, J. C. Coleman, Prof. S. H. Gaiger, Mr. A. Lawson, Lieut.-Col. A. W. Mason, Dr. McI. McCall, Messrs. J. McKinna, W. J. Mulvey, Dr. Share-Jones, Mr. S. H. Slocock, Sir Stewart Stockman, Mr. H. Sumner, Major-General Thomson, C.B., Messrs. R. C. Trigger, G. Thatcher, (Solicitor), and F. Bullock, (Secretary).

*Minutes.* The minutes of the previous meeting, which had been printed and circulated, were taken as read and confirmed.

*Apologies for Absence.* It was announced that letters regretting inability to attend the meeting had been received from Messrs. P. J. Howard, J. Dunstan, P. Wilson, S. Wharam, J. H. Carter and T. Salusbury Price.

*Obituary.* The SECRETARY read the Obituary List. Mr. MULVEY: The last name on the list—Mr. Joseph Woodger, is that of one of the most respected members of our profession. He was a member of this Council some years ago, and a Vice-President, and he acted as Honorary Auditor for many years. He was a well-known veterinary surgeon, and very highly respected. His death is a loss, because the name of Woodger in London and its immediate district has always been held in high esteem. He was certainly one of the best members of our profession; and an ornament to it, and his death is deplored by all who had the pleasure of knowing him. He had attained a great age, so that he was not much known to the younger generation. I beg to move that a vote of condolence be passed with his family in their bereavement.

Mr. TRIGGER: Although I am one of the senior members of the Council, I am afraid that Mr. Woodger was even before my day. I had not the privilege, as those who live in the more immediate neighbourhood of London had, of a close acquaintanceship with Mr. Woodger, but his reputation was well known throughout the profession. Personally I have known him by name for a very long time and I am quite sure the profession at large will endorse the words that Mr. Mulvey has spoken, and wish to join in the vote of sympathy that has been proposed.

The resolution was passed in silence, all present standing.

*Correspondence.* The SECRETARY read the following resolution forwarded by the North of Ireland Veterinary Medical Association, passed at a meeting of the members held at Belfast on the 28th day of March, 1919:—"That this meeting places on record its appreciation of the action of the Government in introducing the Ministry of Health Bill and its application to Ireland. Further, having regard to the invaluable assistance heretofore

rendered by the members of the veterinary profession to the cause of public health, and to the important part which they must in the future undertake in the matter, would point out the necessity of having the words 'and a member of the Royal Veterinary College' added to clause (d) of sub section (2); and at least one member of the veterinary profession on the Irish Public Health Consultative Council; and this meeting requests the Government to provide in such Bill for such representation. That copies of this resolution be forwarded to the Prime Minister, Dr. Addison, the Chief Secretary for Ireland, the Attorney General for Ireland, and the Ulster Members of Parliament."

The SECRETARY read the following resolution passed by the National Veterinary Medical Association on the 10th April:—"The Council of the National Veterinary Medical Association of Great Britain and Ireland, having carefully considered the situation, strongly support the claims of the veterinary officers of the Department of Agriculture and Technical Instruction of Ireland to be included in the Professional Officers' Class of Civil Servants, as in the case of veterinary officers of the Board of Agriculture and Fisheries."

The PRESIDENT: Nothing arises on those resolutions, because they have been dealt with by the different committees.

#### FINANCE COMMITTEE.

Mr. LAWSON read the following report of a meeting of the Finance Committee held on Friday, April 11th, 1919:—

*Financial Statement.* The Treasurer submitted his quarterly financial statement showing a balance in hand of £125 11s. 6d. and liabilities amounting to £146 14s. 6d. It was resolved that the Treasurer's statement be approved, and that he be ordered to pay the liabilities shown together with cheques for monthly salaries, printing of Register, Fellowship examiners' fees, gas, electric light, workmens compensation insurance.

*Voluntary Subscriptions.* The secretary announced that the amount received in voluntary subscriptions for the first quarter of the year was £697 19s. 0d. It was resolved: That the secretary be instructed to issue a further appeal for subscriptions, to be sent out with the Annual Report, and that an expression of thanks be conveyed to those members who have already subscribed.

It was resolved to recommend that the salary of the secretary be increased by £50 per annum as from April 1st 1919. On the motion of Mr. Lawson, seconded by Major Abson, the report was adopted.

#### EXAMINATION COMMITTEE

The PRESIDENT: The report of the work that has been done by the Examination Committee previous to yesterday's meeting has been printed in order that it may be circulated. You will see what a large amount of work has been done by the Committee—work which has been very onerous indeed. I am very sorry that it has been necessary to call meetings of the Committee during the past quarter, but the work of the Council is increasing in every direction, and we must anticipate in the future more Committee meetings between the ordinary Quarterly Meetings. We cannot do without them if we are going to keep pace with the movement that is going on throughout the country.

Mr. MULVEY: As the President has said, several meetings of the Examination Committee have been held during the past quarter, the proceedings at each of which have been confirmed by subsequent meetings, and I therefore propose to read only the Minutes of the meeting that was held yesterday. The Minutes are as follows:—

*Educational Certificates.* Educational Certificates numbered 1847-1854, and 1869-1870 were submitted and approved.

*Applications for Exemption.* Applications for exemption from the preliminary educational examination were submitted from 22 ex-service candidates, in each case accompanied by educational certificates or by testimonials from headmasters. It was resolved, that in the following cases the application be acceded to:—

1804 W. C. Pratt, age 25, Capt. 4 years service.

1830 W. Taylot, age 27, 4 years' service.

1831 H. West, age 19, 1½ years' service. Further application.

1832 C. Mitchell, 2 years' service.

1843 H. Lewin, 10 years' service, 11 Hussars and A.V.C. Recommended for commission 1st Class Army Cert.

1855 A. J. Beeson, age 23, 4½ yrs' service, Coll. Prec. Cert.

1856 A. Robertson, age 22, 4 years service.

1857 H. R. Randle, Corporal, 3½ years service.

1858 F. S. Clayton, Lieut. M.G.C. 4 years service.

1860 R. R. Guyer, Cadet. Medical Prelim.

1861 E. Ollerhead, Lieut, 2½ years service.

1862 W. W. George, Lieut. age 49, R.A.S.C. (Farrier)

1863 Coull, David, 4 yrs service, A.V.C. Scottish Merit Cert.

1864 David Murray, 3 years service, Scottish Int. Cert. Eng. Maths, French, Science, Drawing.

1865 MacKinley, R. F., age 22, 2 years service

1866 N. C. P. Howard, age 21, 3 years service, recommended for Commission.

1867 Joseph McGuigan, age 21 4 years service, Scottish Merit Cert.

1868 T. W. Henderson, 3½ years service, Scottish Int. Cert. Eng. Maths. French, Science, Drawing.

1869 R. B. H. Murray, Scottish Leaving Cert. 1917, Eng. Maths. Latin, French, Science.

1859 W. Davison, Farr. Sergt. C.A.V.C., 4 years service B.Sc. Agriculture, Toronto, entered Edin. Feb. 1919 Exemption also granted from Class A. Exam. (Except Anatomy).

*Applications from Veterinary Students.* Applications from demobilised veterinary students for permission to sit at the July examinations were received, and it was resolved That in the following cases the applications be granted:—

Class A. D. McWhirter, Sergt. R.A.V.C., 3½ yrs. service, entered Edin. 3rd Feb., 1919.

C. S. Jamieson, 3 yrs. service, entered Edin. 4th Feb., 1919.

Ian A. Galloway, 18 in Oct., 1918; called up for military service, sent to R.A.F. Cadet Distribution Dep., arrived there on Nov. 12, sent back home. Entered Edin. Jan., 1919.

J. R. Haddow, 4 yrs. service, entered Edin., Jan., 1919.

Class B. R. L. Connell, passed A (2nd hons., July, 1915, gold medal). Attended R.V.C. Oct. to Dec., 1915; military service Jan., 1916, to Mar., 1919.

R. M. C. Gunn, B.Sc., exempted from part of A, ent'd Edin. Jan., 1919.

Permission was granted to the following ex-service students to sit at the Class A exam. in Dec. next:—

J. Currie, 3 yrs. service Navy. Ent. Glas., Mar., 1919.

W. C. Welsh, Lt. R.F.A.. 3 yrs. „ Edin., Apr., 1919.

*Colonial Graduates.* Applications were submitted by the Deputy Director-General, Repatriation and Demobilisation Department, Australian Imperial Forces, from the following officers of the A.A.V.C., for permission to sit at the final examination for the Diploma of M.R.C.V.S., after an attendance of two terms at an affiliated Veterinary College.

Lt.-Col. T. Matson, B.V.Sc., Univ. of Melbourne.

Capt. R. A. B. Stanhope, B.V.Sc. „ „

Capt. J. S. Penrose, „ „ „

Capt. G. Fethers, „ „ „

Capt. H. R. Seddon, „ „ „

Major T. H. Hankin, „ „ „

Major C. T. McKenna, „ „ „

Major L. E. McKenzie, D.V.Sc. " Berne, Switz'd.  
 Major R. H. F. MacIndoe, L.V.Sc. " Melbourne.  
 Major F. Murray Jones, " " "  
 Capt. F. V. Collins, " " "  
 Capt. F. C. E. Geyer, B.V.Sc. " Sydney.  
 Major E. S. James, " " "  
 Capt. B. C. Veech, " " "  
 Capt. W. L. Hindmarsh, " " "

In each case the officer was recommended by the Deputy Director of Veterinary Services to the Australian Imperial Forces. It was resolved to recommend that the applications be acceded to.

Applications were submitted by the Director of Veterinary Services of the Canadian Army Veterinary Corps on behalf of officers of the C.A.V.C. for permission for them to sit at the final examination for the Diploma of M.R.C.V.S. after attendance for two terms at an affiliated Veterinary College. It was resolved to recommend that the applications be granted in the cases of the following officers:—

Capt. H. Colebourne, B.V.Sc., Toronto, 1911.  
 Capt. E. L. Brown, B.V.Sc., Toronto, 1917.  
 Lieut. O. V. Gunning, D.V.M., Ohio, 1917.  
 Major C. G. Saunders, D.S.O., B.V.Sc., (Hons.) Toronto, '09.  
 Capt. R. M. Lee, B.V.Sc., Toronto, 1916.

*Government Maintenance and Training Grants to students.* A letter from the Ministry of Labour was received confirming the proposals reported by the President at the previous meetings:—

Ministry of Labour, Civil Demobilisation and Re-settlement Department,

8 Richmond Terrace, Whitehall,

Ref. No. D.R.A. 203/17. London, S.W.1, April 2, 1919

Sir,—I am directed by the Minister of Labour to refer to the proposal which was communicated to the Lords Commissioners of H.M. Treasury by the Secretary of the Board of Agriculture and Fisheries in his letter dated the 16th January, 1919. It is understood that you are in possession of a copy of this letter.

I am to inform you that it has now been agreed between the Board of Agriculture and Fisheries and the Ministry of Labour that the selection of scholars and the payments of grants for training in veterinary surgery under the Ministry of Labour will be carried out in accordance with the general principles of the Officers University and Technical Training Committee scheme for the assisted training of Officers and other ranks of similar educational qualifications.

In this connection I forward copies of letters addressed to the Board of Agriculture and Fisheries and to the Scotch Board of Agriculture, and the Department of Agriculture and Technical Instruction for Ireland.

If you agree to the proposals therein contained, the Minister would be glad to be informed of the names of the members of the Council of the Royal College of Veterinary Surgeons who will be on the Sub-Committee of the Central Grants Committee.

I am to state that Sir Robert Horne has nominated Major the Hon. J. N. Ridley, Secretary of the Grants Committee, for the post of Chairman of the Sub-Committee, and that it is understood that the secretarial work of the Sub-Committee will be carried out by the Secretary of the Royal College of Veterinary Surgeons. I am, Sir, your obedient servant,

J. A. BARLOW.

The President, R.C.V.S., 10 Red Lion Sq.

D.R.A. 203/17. 31st March, 1919.

Sir,—I am directed by the Minister of Labour to refer to the letter addressed to you on Jan. 16th, 1919, by the Secretary of the Board of Agriculture and Fisheries, and to state that it has now been agreed with the Board of Agriculture and Fisheries that the Ministry of Labour will be responsible for administering the training of

veterinary surgeons under the terms of the Officers' University and Technical Training Committee scheme for assisted training of officers and other ranks of similar educational qualifications.

It is proposed that the selection of scholars for training in the veterinary colleges of the United Kingdom shall be carried out by an Advisory Committee, which will operate as a Sub-Committee of the Grants Committee of the Ministry of Labour, and which will consist, as proposed by the Secretary of the Board of Agriculture and Fisheries in his letter to the Treasury dated Jan. 16th, 1919, of the following members:—

One representative of the Board of Agric. and Fisheries.

" " " Dept. of Agric. and Technical Instruction for Ireland.

" " " Board of Agric. for Scotland.

Five members of the Council of the Royal College of Veterinary Surgeons, not connected with the schools. A Chairman to be nominated by the Ministry of Labour.

The Minister would be glad to be informed if your Department concurs in this proposal, and, if so, to receive the name of your representative appointed to serve as a member of the Advisory Committee.—I am, Sir, your obedient servant,

(Sgd.) J.A.B.

The Secretary, Dept. of Agric. and

Technical Instruction for Ireland, Dublin.

A copy of this letter was addressed also to The Secretary, Board of Agriculture for Scotland, 29 St. Andrew Square, Edinburgh.

31st March, 1919.

Sir,—I am directed by the Minister of Labour to refer to your letter dated March 13th, 1919, and to state that the arrangements, semi-officially agreed upon between your department and Major Ridley on the 10th inst., are concurred in.

It is proposed that the selection of scholars for training as veterinary surgeons under the scheme for the assisted training of officers and other ranks of similar educational qualifications shall be carried out by an Advisory Committee composed as was suggested in your letter of 16th January, 1919, addressed to the Treasury, and operating as a Sub-Committee of the Grants Committee of the Minister of Labour.

I am directed to request that Sir Robert Horne may be informed of the name of the representative appointed by Lord Ernle to serve as a member of this Advisory Committee.—I am, Sir, your obedient servant,

(Sgd.) J.A.B.

The Secretary, Board of Agric., and

Fisheries, 4, 5 and 8 Whitehall Place, S.W. 1.

The Secretary reported that he had informed the Ministry of the names of the representatives of the College, as approved by the Committee at its previous meeting.

*Dates of Professional Examinations.* The Secretary reported that he had been asked by Secretaries of the Schools to supply information with regard to the probable dates of the professional examinations during the coming year. It was resolved to recommend that the Council at its meeting in July should fix the following dates for the professional examinations:—

1919 Dec. 12 Written. 1920 July 5 Written.  
 16 Oral. 6 Oral.

*Bye-laws.* It was resolved to recommend That a special Committee be appointed by the Council to consider the Bye-laws of the College, and to recommend necessary revisions.

*Instructions to Examiners.* The Secretary submitted a draft of instructions to Examiners, and it was resolved That the draft be printed and circulated to the Committee before its next meeting.

The following Minutes of meetings of the Examination Committee held since the previous quarterly meeting were taken as read :—

*Examination Committee.* The following are reports of the meetings of the Examination Committee, held on Friday, February 28th, and Friday, 21st March 1919.

*Present*—Mr. W. J. Mulvey in the Chair; Mr. F. W. Garnett, Sir John M'Fadyean, and Mr. S. H. Slocock.

February 28th, 1919

*Minutes.* The Minutes of the previous meeting, having been printed and published, were taken as read and confirmed.

*Educational Certificates.* Educational Certificates numbered 1780, 1792, 1795, 1810, 1825, 1826, 1827 were submitted and approved.

*Applications for Exemption.* Applications for exemption from the preliminary educational examination were received from 31 ex-service officers and men, in each case accompanied by educational certificates or testimonials from headmasters and others. In the following cases the applications were acceded to :—

- 1793 Buchanan, J. H. Higher Ed. Scotland Inter. Cert.
- 1794 Amar Nath, Graduate of Lahore Vet. College. Dallwall Middle School Certificate.
- 1796 Blacklee, E., (M.C.) Lieut. Oxford Junior and Senior Certs.
- 1797 Walker, F., 4 years service. Trained Certificated Teacher.
- 1799 Bowie, R. S. Lieut. 4 yrs service Head Master's Cert.
- 1801 Bryan, R., Lieut. 3½ yrs. service " "
- 1802 Ford, L. J., Lieut. 3½ yrs. service " "
- 1803 Clegg, A. C. 4½ yrs. service. wounded " "
- 1805 Nichols, J. H., Private 1 yrs. service. (Cambridge Junior and Ed. Inst. Scotland Prelim.
- 1806 Bristow, R. Lieut. 4½ yrs service Head Masters Cert.
- 1808 Carter, J. G. Lieut. 3 years service " "
- 1809 Jones, W., Private, 15 mths service " "
- 1811 Catmur, M. G. 2 yrs. service wounded " "
- 1814 McGowan, A. G., Lieut. 3½ yrs service. Cambridge Junior Cert. and Chartered Accountants' Prelim.
- 1815 Robinson, T. H., Lieut. Irish Intermediate Middle Grade Cert.
- 1816 Braes, J. R. M. 4½ yrs. service Head Master's Cert.
- 1817 Lauder, D. J., 2 yrs. service. Scottish Inter. Cert.
- 1824 Bryden, W. P., Lieut. 2 yrs. service. " "
- 1828 Barker, E. D., 4 years service. Head Master's Cert.

The following cases were considered, and it was resolved That the applications be acceded to provided that satisfactory certificates as to general education be received.

- 1804 Pratt, W. C., Capt., 4½ years service. Wounded.
- 1821 Crumplin, C. H., Lieut., 3 years service.
- 1812 Renfrew, A. R., Flight Cadet, 2½ years service. Cambridge Junior and Senior Certs. English, Maths., Latin, Heat, Practical Physica.

It was resolved That A. R. Renfrew's preliminary certificates be accepted, and that he be admitted to the Class A examination in December, 1919, provided satisfactory certificates as to attendance are received.

*Special Application.* 1822 Mitchell, H. D., Lieut. B. Sc. Degree in Agriculture, McGill University, 1915.

It was resolved That this applicant be granted exemption from the preliminary educational examination, and also exemption under the provision of Bye-law 62a from the first professional examination.

*Applications from Veterinary Students.* The following applications were received from veterinary students :—

A. A. Hamilton. Class B. Attended Dublin, Oct., 1917 to March, 1918, and Oct., 1918 to Nov. 14, 1918. Applies for permission to count attendances at Glasgow from Jan., 1919 to July, 1919, and to sit at Class B exam. in July, 1919. Resolved That the application be not acceded to.

M. W. Sheppard. Class B, passed A 2nd. Hon., July, 1916. Attended Class B, Oct. to Dec., 1916. Military service since. Leave granted to sit at B exam. in July, 1919.

J. E. Barnes, Capt., Class D, 3½ years' service. Discharged unfit, Feb., 1918. Passed Class C, 2nd. Hons. Dec., 1918. Leave granted to sit at D exam in July, 1919.

J. R. Pratt. Class D. Passed C July, 1918. Served R.A.V.C., August, 1918 to Jan., 1919. Leave granted to sit at D exam. in July, 1919.

M. Bridgeman. Class B. Passed Class A, July, 1916. Attended two terms Class B. Military service, March, 1917 to Dec., 1918. Is taking B exam. July, 1919. Applies to take C exam. in Dec., 1919.

It was resolved That the application be not acceded to. W. Coulter. Failed Anatomy Class A, Dec., 1914 4½ years' service. Leave granted to sit at B exam. in Dec., 1919, and to be examined in the whole subject of Anatomy.

J. Ferguson. Class B. Attended Glasgow, Oct. to Dec., 1915. 3 years' military service. Rejoined Feb. 5th, 1919. Leave granted to sit at B exam. in July, 1919.

R. Scoular. Class B. 3 years' service. Demobilised, Feb., 1919.

Resolved to recommend : That in view of the applicant's military service, he be allowed to present himself for the Class B exam. in July, 1919, on producing evidence that he has attended for two terms at a veterinary college.

R. R. Moodie. Class B. 3 years' service. Demobilised Feb., 1919. Leave granted to sit at Class C exam., July, 1919.

R. R. Watts. 4½ years' service. Failed Anatomy, July, 1914. Class B. Leave granted to pass to C Course and to sit for Senior Anatomy in July, 1919, and, if successful, at the Class C exam., Dec., 1919.

J. N. P. Holt. 4 years' service. Rejected Class B, Dec., 1913 and July, 1914. Applies to pass to Class B, and to sit for Anatomy and Physiology, July, 1919.

Resolved : That the application be not acceded to. J. H. P. Games. Class A. 4 years' service. Failed Class A, July, 1909. Applies to pass to Class B.

Resolved : That the application be not acceded to.

J. Mair. Class B. 3 years' service. Demobilised Jan. 31, 1919. Leave granted to sit at B exam., July, 1919.

F. E. Somer. Class B. 2 years' service. Demobilised Jan. 15, 1919. Leave granted to sit for Class B exam., July, 1919.

In all the above cases, the concessions granted are conditional upon the receipt of satisfactory certificates from the colleges attended.

*Stellenbosch University.* An application was received from the University of Stellenbosch for the admission of students who have passed the first year's examination of the University in Chemistry, Physics, Botany and Zoology to the second year's course for the diploma of M.R.C.V.S.

It was resolved : That the consideration be deferred pending the receipt of further information from the University

*Colonial Veterinary Surgeons.* (a) An application was received from Mr. W. E. Armstrong, B.V. Sc., (Toronto, 1915), Capt. R.A.V.C., for permission to attend at the final year's course and to sit for the final examination for the diploma of M.R.C.V.S. It was resolved to recommend That under the provision of Bye-law 61a, the application be acceded to.

(b) An application was received from Colonel E. A. Kendal, C.M.G., of the Australian Imperial Forces asking what concession if any, could be granted to Australian Veterinary Surgeons at present holding commissions in the A.A.V.C., who desire to obtain the diploma of M.R.C.V.S. The Secretary was instructed to reply that the Committee would be prepared to

recommend, in the case of holders of the degree of Bachelor of Veterinary Science, that permission be given such candidates as are recommended by the Australian Army Authorities to sit for the final examination for the diploma of membership, after a satisfactory attendance for two terms at one of the affiliated veterinary colleges. The Committee were not, however, prepared to deal with the case of veterinary officers not holders of the degree of B.V.Sc., without further consideration after the receipt of a more detailed application.

*Woman Applicant.* A further application was received from Miss E. G. Knight for consideration of her request, but the Secretary was instructed to reply that no decision was possible at present other than that already communicated to her.

March 21st, 1919.

*Present*—Mr. W. J. Mulvey in the Chair; Dr. O. Charnock Bradley, Mr. F. W. Garnett, Sir John M'Fadyean, Mr. J. McKinna, Prof. E. S. Shave, Mr. S. H. Slocock, and Sir Stewart Stockman.

*Minutes.* The minutes of the previous meeting were read and confirmed.

*Educational Certificates.* Educational Certificates numbered 1844, 1845, 1846, were submitted and approved.

*Applications for Exemption.* Applications for exemption from the Preliminary Educational Examination were received from 22 ex-service officers and men, in each case accompanied by certificates or testimonials from headmasters. It was resolved That exemption be granted in the following cases:—

- 1807 Robertson, T., Age 21, Two years' service.
- 1819 Miller, J. C., Capt. R.A.V.C., Age 34, Graduate San Francisco Veterinary College.
- 1821 Crumplin, C. H. Lieut. Age 25. Four years' service College of Preceptor's Certificate, 3rd Class
- 1823 Byrne, P., Corporal. Age 20. 2½ years' service
- 1829 McGeachy, A. Age 22. Four years' service.
- 1835 Burgon, E. A., Staff Sergeant R.A.V.C. Age 22.
- 1836 Longmuir, W., Sergt-Major. Age 28. 4½ years' service.
- 1837 Wooldridge, W. R. Age 18. One years' service London School Cert. (Eng., Maths., Hist. and Geog., French, Drawing, Heat, Light and Sound, Mechanics, Chemistry); London Matric. (Eng., Maths., French, Hist. and Geog., Heat, Light and Sound, Drawing); Inter B.Sc., (Pure Maths., Applied Maths., Physics, Chemistry).
- 1838 Granshaw, W. A. Age 20. Two years' service. London Senior School Cert. (Eng. Mathematics, French, Heat, Light and Sound, Chemistry and Mechanics).
- 1839 Brennan, A. D. T., Lieut. Age 24. 4½ years' service. Irish Int. Middle Grade (Eng., Maths., Hist. and Geog., Latin, French, German, Physics. Senior Grade (Eng., Maths., Latin, French, German, Chemistry).
- 1840 Griffiths, H. W., Sergt. 2 yrs. service Testimonials
- 1841 Smithies, R. B., Sergt. R.A.M.C. 4½ years service. College of Preceptors' Junior Certificate.
- 1842 Wilkins, H. C., Lieut. 4½ years service. Wounded. Central Welsh Board Senior Cert., 1st B.D.S. (Chemistry, Physics, Zoology); 2nd B.D.S. (Dental Mat., Med., and Metallurgy). Exemption was granted from part of the first year's examination, conditional upon the candidate taking the whole subject of Anatomy at the Class B Exam.)

*Applications from Veterinary Students.* (a) An application was received, signed by 78 veterinary students recently demobilised from the Army, for a modification of the rules concerning the professional examinations.

It was resolved That the applicants be informed that the Committee cannot recommend the Council to grant their request, but that applications from individual

students will be sympathetically considered by the Committee after the examinations in July, each case being dealt with on its merits.

(b) Applications were received from 16 veterinary students recently demobilised for permission to sit at the Professional examinations to be held in July.

It was resolved That on the production of satisfactory certificates of attendance, the following students be admitted to the July examinations.

Class A. J. W. Thwaite, E. Wilkinson, A. Fulton, J. H. Bateman, W. R. Wallace.

Class B. A. W. Baird, T. W. M. Cameron, W. Coulter, C. H. Dicksbury, R. Dunwoody, A. M. Graham, F. J. Hood, A. J. McCarmick, T. J. Richardson.

*Government Maintenance and Training Grants.*

(a) The following letter was received from the Board of Agriculture:—

Board of Agriculture and Fisheries,  
I.2582/1919. Whitehall Place, London, S.W. 1.

13th March, 1919.

Sir,—In reply to your letter of the 17th ult., I am directed by the President of the Board of Agriculture and Fisheries to refer to the Conference which took place at this office on the 10th inst., and to say that in accordance with the decision then taken, the Board are withdrawing their application to the Treasury for funds for the training of veterinary students who have served in His Majesty's forces during the War. The Board of Agriculture for Scotland, and the Department for Agriculture and Technical Instruction for Ireland, are being informed to that effect.

It is understood that the necessary provision will be made by the Ministry of Labour in the case of the Veterinary, as in other professions.—I am, Sir,

Your obedient servant,  
(Sgnd.) A. D. HALL, Secretary.

(b) The President reported that he had had an interview with Major Ridley of the Appointments Department of the Ministry of Labour, with regard to the method of awarding grants to ex-service officers and men desirous of completing the course for the Diploma of M.R.C.V.S., and to other candidates of the same class desirous of entering upon the course. The Veterinary Profession had now been included amongst the professions for which training grants can be made by the Ministry of Labour in all approved cases, and it was proposed that a special Sub-Committee consisting of representatives of the veterinary profession not connected with the Schools, and representatives nominated by the Boards of Agriculture for England and Scotland, and the Department of Agriculture for Ireland, with a Chairman to be appointed by the Ministry of Labour, should be formed for the purpose of investigating all applications. The President had submitted the following names to the Ministry of Labour as representatives of the profession on the proposed Committee:—G. A. Banham, J. Clarkson, F. W. Garnett, S. H. Slocock, P. Wilson. It was resolved That the action of the President be approved.

*Correspondence.* A letter was received from the Secretary of Agriculture for the Union of South Africa asking for an expression of opinion from the Council as to the degrees or diplomas in veterinary science granted outside the United Kingdom which may be regarded as equivalent to the M.R.C.V.S. in their standard of attainments in veterinary science. It was resolved That the Secretary be instructed to reply that the Council have not before them the information which would enable them to answer the question put.

Mr. TRIGGER: I think the profession will be very anxious to be assured, in regard to the various applications that have been made by service men, that it is a war emergency measure only.

Mr. MULVEY: You may be quite assured of that.

The Committee have been very careful indeed and only men who have done good service have been considered.

Mr. TRIGGER: I am perfectly well aware of it myself, but I think the fact ought to go out to the profession, in order that there may be no doubt about it.

The PRESIDENT: They also come under the special Bye-law which was passed by this Council as a war emergency measure.

Major-Gen. BLENKINSOP: Certain applications have been granted in the case of Canadian and Australian officers of the Army Veterinary Corps, but I should like to point out to the Council that in addition to the officers who have been put forward there were at the termination of hostilities no fewer than 126 Canadian graduates serving in the Royal Army Veterinary Corps, several of whom were quite as highly qualified and have done quite as good work as the officers to whom you have given exemption.

The CHAIRMAN: I should like to point out to Gen. Blenkinsop that if any applications are made they will be considered in the same way as the other applications, but up to the present no other applications than those which have been read out have been received by the Committee. They will all be considered if application is made.

Major-Gen. BLENKINSOP: The point I want to make is that nobody knew anything about the applications or that anything was being done in regard to the matter. Some of these officers may be on their way to Canada by now. When the Committee was considering the subject, if they had only given us the information we could have told the Canadian graduates before they proceeded overseas. Many of the graduates that I am speaking about came over here in the early part of the war to assist us during a very difficult time; many of them have now returned to Canada and of course have lost any opportunity they might have had under this arrangement.

The PRESIDENT: I can assure Gen. Blenkinsop that what he is complaining about having been omitted has been done through the respective Army Veterinary Corps, both the Australian and the Canadian.

Major-Gen. BLENKINSOP: I am speaking of the Royal Army Veterinary Corps. At first we had the Canadian Army Veterinary Corps officers and 77 Australian officers, all of whom were serving under the Director General of Veterinary Services in different theatres of the war. Some of them were not serving under the Deputy Director of Veterinary Services at all, and never have done so. The officers I am speaking about number 126 or more—I believe many more. When the armistice was signed there were about 126 Canadian graduates in the Royal Army Veterinary Corps.

Mr. MULVEY: I should like to say, by way of explanation, that no information was sent to anyone connected with any of the Colonial Forces in regard to this matter; the application came from them. The application in the first instance came from Col. Kendall by way of a request. He was then told that individual application must be made in each case. But no information was ever sent, and no request was ever made to anyone. The result of that is that all the applications that have been made are personal applications, and it was open to anyone connected with the Colonial Forces or any veterinary students to make application in the same way.

Col. BRITTLEBANK: With regard to the matter raised by Mr. Trigger, I am not quite clear, although I am a member of the Examination Committee, whether the question of granting these applications of Colonial graduates is to be considered as a war measure or as an honour. What is it? Are we conferring honours from this College on these people?

The PRESIDENT: No. They are going to pass the examination.

Mr. SUMNER: After six months' study.

Mr. MULVEY: We are not conferring anything at all upon them. I thought that was made quite clear yesterday at the meeting of the Committee.

Col. BRITTLEBANK: I was quite clear with regard to the facilities given to the men who were excused from the Preliminary examinations as far as students were concerned, but I did not understand that the doors of this College were to be opened to these graduates of Melbourne University or the various Colleges that these people come from. I am not saying it is unwise nor that it is wrong, but it is creating a precedent which it seems to me is going to be extremely difficult to govern in the future. Have you powers to restrict it purely and simply to men who have served in the Royal Army Medical Corps, so that it will not go beyond that?

Mr. MULVEY: That is so. You may rest assured that that was the understanding, and that that was the instruction of the Council to the Committee—that it was to be to men who had served in the Army during the present war, and those men only.

The PRESIDENT: Practically the whole of the work of the Examination Committee is consequential on the special Bye-law that the Council passed in regard to war services.

Col. BRITTLEBANK: I hope the Council will forgive me for pleading ignorance. I know that ignorance is no excuse for breaking the law, but I am ignorant of the proceedings in regard to this matter, and it was merely from the point of view of the danger of creating a precedent that I rose to ask the question. I think, in fairness to the other graduates that General Blenkinsop has mentioned, whether they have returned to Canada or not, it should definitely go forth from this Council that any recommendations coming from the Director-General will receive very careful consideration by this Council, whether these people have gone home or whether they are still serving.

The PRESIDENT: They have only to make application to this Council.

Col. BRITTLEBANK: But that is not understood. It is quite evident that the Director-General did not understand it.

The PRESIDENT: As I say, they have only to make application to this Council. I take it that those men who wanted the degree have made application at the present time.

Col. BRITTLEBANK: But none of these men seem to have the faintest idea of these particular facilities which they may claim.

Sir STEWART STOCKMAN: Is it not open to Gen. Blenkinsop to tell these men that they may apply?

The PRESIDENT: They must submit their names and qualifications individually for the consideration of the Examination Committee.

Sir STEWART STOCKMAN: But is it not open to Gen. Blenkinsop or anybody else to tell these gentlemen about it?

The PRESIDENT: Yes. Gen. Blenkinsop can do what he likes in the matter? we have no power over him.

Mr. McKINNA: And I hope that Col. Brittlebank will do the same too.

Dr. SHARE-JONES: Is it not the fact that bringing the matter before the Council is the only means at our disposal of conveying this fact to the whole profession?

The PRESIDENT: That is so.

Dr. SHARE-JONES: It will be quite well known after this afternoon.

On the motion of Mr. Mulvey, seconded by Dr. Bradley, the reports of the meetings of the Examination Committee on February 28th, March 21st and April 10th, were adopted.

On the motion of Mr. Mulvey, the following gentlemen were appointed a Special Committee to consider

the Bye-laws of the College, and to recommend the necessary revisions:—The President, Messrs. McKinna, Share-Jones, Gaiger, Bradley, Mulvey, Sir John M'Fadyean and Mr. Howard.

#### PARLIAMENTARY AND GENERAL PURPOSES COMMITTEE.

Dr. BRADLEY read the following report of a meeting of the Parliamentary and General Purposes Committee held on April 10th.

*Clean Milk Supply.* The Secretary reported that the Sub-Committee on the Clean Milk Supply, in the absence of a quorum, were unable to submit a report.

*Ministry of Health Bill. Scottish Board of Health Bill.* These Bills were submitted and considered. The Solicitor reported that the Ministry of Health Bill had passed its third reading on April 9th, and that the Scottish Board of Health Bill had passed the Standing Committee. He had attended all the sittings of the Standing Committee, and with the President, had had interviews with the Secretary for Scotland and the Attorney General for Ireland. He submitted a report on the steps taken, in consultation with the President, to secure adequate representation of the veterinary profession.

It was resolved That strong representations be made to the Minister, after passing the Ministry of Health Bill, that a representative of the veterinary profession should be appointed on the Board for Ireland, and on the Consultative Council for England. That similar efforts be made for the appointment of a representative of the profession on the Consultative Council under the Scottish Board of Health Bill. That a circular letter be sent to all the Veterinary Medical Associations urging upon them the advisability of taking such local action as was immediately possible to them in order to secure proper representation of the profession.

*Dogs Protection Bill: Vivisection of Animals Bill.* These two bills were submitted and considered. The Solicitor reported that the Dogs (Protection) Bill had already passed through Committee. It was resolved That it be left to the President and Solicitor to take such steps as they consider desirable in support of the opposition to these bills.

*Animals (Anaesthetics) Bill.* This Bill was submitted and considered. It was resolved That no action be taken.

*Mettam Petition.* Information was received to the effect that there was no further necessity to proceed with the collection of signatures to this Petition.

*Civil Liabilities.* The Secretary submitted copies of the Regulations made by the Military Service (Civil Liabilities) Committee, showing the circumstances in which assistance may be given to demobilised officers, and the procedure for making an application.

*Women's Emancipation Bill.* The Secretary called attention to Clause 1 of the Women's Emancipation Bill now before Parliament which provides for the removal of the sex disqualification and it was resolved That the matter be referred to the Annual Fee Committee.

The following report of a meeting of the Parliamentary and General Purposes Committee held on March 21st, 1919, was taken as read:—

*Parliamentary Bills.* The Solicitor reported that Messrs. Sherwood and Co. having perused the Private Bills deposited for the present session, do not find that any affect the interests of the College and the Profession.

*Ministry of Health Bill.* The Ministry of Health Bill was submitted together with copies of resolutions passed by the Midland Counties V.M.A., the Royal Counties V.M.A., and the Veterinary Medical Association of Ireland with regard to the Bill. The Solicitor reported that he had been in attendance at the Stand-

ing Committee of the House of Commons during the consideration of the Bill, and that on the instructions of the President, he had endeavoured to make arrangements for an amendment to Clause 9, providing for the inclusion of a veterinary surgeon in the Scottish Board of Health, as constituted by Sub-section iii. of Clause 9.

It was resolved to recommend (a) That having given the most earnest consideration to the provisions of the Bill, the Committee do not consider, in view of the fact that the Bill does not enact any new legislation on matters of interest to the profession, but merely brings together under one department the functions of several departments under existing Acts of Parliaments, that there is any opportunity in the present Bill for intervention on the lines suggested in the Resolutions submitted.

(b) That the Solicitor be instructed to continue to watch the progress of the Bill.

(c) That the President be authorised to continue his endeavour to obtain the inclusion of a Member of the Royal College of Veterinary Surgeons in Clause 9, Sub-Section iii., in the event of the Bill being applied to Scotland.

*Furriers' Registration Bill.* A copy of the draft Furriers' Registration Bill was submitted, together with resolutions on the matter passed by the London Furriers' Association, and by the Lancashire Veterinary Medical Association. After due consideration it was resolved That no action be taken for the present.

*Demobilisation of Veterinary Surgeons.* The President reported that he had ascertained by means of a question put in the House of Commons on Thursday, March 13th, that up to that date 132 veterinary officers had been released from the Royal Army Veterinary Corps since the Armistice.

It was resolved That the Secretary be instructed to write to the Secretary of the War Office pointing out that out of more than 1100 veterinary surgeons on Active Service, only 132 had been demobilised by March 13th, and requesting that in view of the great dearth of veterinary surgeons in civil practice throughout the country, every possible effort be made to demobilise a large proportion of civil veterinary practitioners as early as possible.

The Secretary reported the receipt of the Animals (Notification of Disease) Order of 1919 from the Board of Agriculture.

Sir STEWART STOCKMAN: May I ask when the Sub-Committee on the Clean Milk Supply was to have met?

The PRESIDENT: It was to have met at 11 o'clock yesterday morning, but in the absence of a quorum it was unable to do so.

Sir STEWART STOCKMAN: That is exceedingly unfortunate, because the matter is being pushed on, and any report that the Sub-Committee desire to make should have been presented today. The thing is in process of being formed; they are pushing on with it as hard as they can, and it would have been of great benefit if we could have had the views of that Sub-Committee on the subject. I do not know if anything can be done.

Mr. MULVEY: Not a single member turned up.

The PRESIDENT: I do not think we can do anything now.

Sir STEWART STOCKMAN: It will be too late in the week if you want to do anything.

The PRESIDENT: If that is so we can call a meeting of the Sub-Committee this afternoon after this meeting. The Committee consisted of Sir John M'Fadyean, Mr. Price, Mr. Slocock, Col. Brittlebank and myself.

Col. BRITTLEBANK: What object would there be in the Committee meeting to-day? The Council cannot receive its report. I suggest that if anything is to be done it ought to be done now. The Sub-Committee, if it met, could not do anything.

Mr. TRIGGER: Unless you gave it executive powers.  
Major ABSON: Cannot we go into Committee and deal with the matter now?

The PRESIDENT: Yes, there is no reason why the Council should not resolve itself into Committee and deal with the question, so that immediate action can be taken.

Mr. McKINNA: I propose that the Council resolve itself into Committee to deal with the matter now. Dr. McCall seconded the motion, which was carried unanimously.

Mr. THATCHER: Before the Council goes into Committee, I should like to say, with regard to the Scottish Board of Health Bill, that the statement made in the report that the Bill had passed the Standing Committee was quite correct at the date of the meeting, but since then, namely, last night, the Bill had passed its third reading.

The PRESIDENT: Before we go into Committee I think it would be better to pass the reports of the Parliamentary Committee.

Dr. BRADLEY: I move that the minutes of the meetings of the Parliamentary Committee of March 21st and April 10th, be adopted. Mr. McKinna: I second that.

The CHAIRMAN: There is one matter in the report of the Parliamentary Committee to which I think it would be as well to draw the attention of the members of the profession, namely, the new regulations under the Military Service Civil Liabilities Committee. Apparently members of the profession who have had to close down their practices will be dealt with under this Order. They may be able to get, and most probably will get, certain sums of money at the discretion of the Commissioners, who will go into the question of the liabilities and of the sacrifices that veterinary surgeons have made owing to the closing down of their practices.

The motion for the adoption of the reports was then put and carried unanimously.

The Council then resolved itself into Committee for the purpose of discussing the question of clean milk supply.

On the Council resuming its sitting in public, it was announced that the following resolution had been passed by the Committee: "That the attention of the Local Government Board, the Ministry of Food, and any other Government Department concerned, be drawn to the fact that much technical and administrative work is now being done by unqualified persons in connection with the work of the Food Control Committees, which, in the interests of efficiency and public health, should be done by qualified veterinary surgeons." It was also decided to recommend that the following additional names be added to the Sub-Committee:—Messrs. Share-Jones, McKinna, Coleman, Abson and Banham.

Col. BRITTLEBANK: I feel it my duty, as perhaps the original mover in this matter, to speak in regard to the formation of this Committee. The position, as I have already said in Committee, in which the profession finds itself under this scheme for the production of milk of higher grades is a most unfortunate one, and I hope it will go out from this Council as a very strong expression of opinion that they view with a considerable amount of disfavour the ready manner in which veterinary surgeons have allowed themselves to act, or lent themselves, in a menial capacity, in carrying out the scheme which has been promulgated by the Food Production Department. The veterinary surgeon plays but a very small part in it. The scheme as originally drawn up has, I am bound to say, many points to recommend it. It is an attempt at any rate to do something in a direction in which genuine work is very badly required; but until the profession gets its full share of recognition in the matter—its full share of recognition consisting in nothing short of complete control of the whole question,

as it is a matter concerned with the housing and well-being of cattle, the modes and methods of milking, and everything applicable to the general conduct of the very large business of dairying—we ought not to be satisfied. We come into intimate connection with the Public Health Service, and until we obtain the position which we claim is our right, I consider that our brethren in practice should refuse strenuously to have anything to do with the matter. I do hope that this Council will express itself very strongly on the subject, as a lead to the profession in general. We have a definite claim to these positions, and only by asserting it shall we get them.

On the motion of Dr. Share-Jones, seconded by Mr. Coleman, the report of the Committee was received and adopted.

Mr. COLEMAN: Has that Committee executive powers?

The PRESIDENT: Yes.

#### REGISTRATION COMMITTEE.

The PRESIDENT: I am sorry to say that we have not a quorum present for the purpose of dealing with the report of the Registration Committee.

The SECRETARY read the report of a meeting of the Registration Committee held on April 10th., from which it appeared that 20 cases were considered by the Committee.

Mr. Joseph Randolph Welsby a Member of College was summoned to appear to show cause why his name should not be struck off the Register, he having been convicted of bigamy. The Secretary stated Mr. Welsby had written to him asking for the matter to be adjourned, and he had answered that Mr. Welsby must attend and he produced a telegram he had just received that Mr. Welsby could not be present. The Committee decided to proceed with the case. The Solicitor read a certified copy from the clerk of the Central Criminal Court that on Tuesday 23rd April 1918, Mr. Joseph Randolph Welsby was convicted on an indictment that he married Elizabeth Adelaide Canner during the life of his wife Mildred Mary, and was ordered to be imprisoned and kept to hard labour for 12 months.

The Committee report that they find the conviction proved.

In the remaining cases the Solicitor or the Secretary was instructed in regard to the action that should be taken.

On the motion of Col. Brittlebank, seconded by Dr. Share-Jones, the report was received and adopted, and on the motion of Dr. Share-Jones, seconded by Col. Brittlebank, authority was given for the Seal of the College to be attached to the prosecutions recommended in the report.

#### HONOURS AND PRIZES COMMITTEE.

On the motion of Mr. BANHAM, the following report of a meeting of the Honours and Prizes Committee, held on the 10th April, was received and adopted:—

*Honorary Associateship.* It was resolved to recommend That the Secretary be authorised to take steps to prepare a list of distinguished veterinary surgeons who have rendered conspicuous services to the Allies during the war, and to present the same to the Committee at its next meeting with a view to recommendations for election to the Honorary Associateship of the College.

#### ANNUAL FEE COMMITTEE.

On the motion of the PRESIDENT, seconded by Major ABSON, the following report of a meeting of the Annual Fee Committee held on the 11th April, was received and adopted:—

*Amendment Bill.* Mr. Garnett submitted copies of correspondence relating to the introduction of the Amendment Bill into Parliament and It was resolved

That the matter be left in the hands of Sir John M'Fadyean with power to arrange for the introduction of the Bill at the earliest possible moment.

*Women's Emancipation Bill* The resolution passed by the Parliamentary Committee at its meeting on April 10th was considered and the provisions of the Women's Emancipation Bill were read. It was resolved That no alteration be made in the provisions of the Veterinary Surgeons Act (Amendment) Bill, but that the Council be asked to consider at its meeting in July the desirability of seeking power to admit women to the examinations qualifying for the Diplomas.

#### THE CENTRAL VETERINARY SOCIETY. [NATIONAL V.M.A.—SOUTHERN BRANCH.]

The Forty-fifth Annual Dinner was held on Tuesday, 11th March, at the Holborn Restaurant, London. Fifty-five sat down; Professor G. H. Wooldridge, President, presiding.

The Toast of the King was duly honoured.

##### "THE IMPERIAL FORCES"

Mr. J. WILLETT: Mr. President, ladies and gentlemen, the toast I have the honour to propose is that of "The Imperial Forces"—I should rather say "The Navy, Army, and the Imperial Forces." This toast needs no eulogy of mine for it to be drunk with enthusiasm. The glorious deeds of the Navy and of the Army are so recent in our minds that any words I could say would be invidious. But there is one branch of the Imperial Forces with which we are intimately connected, and about which I should like to say a few words—the Royal Army Veterinary Corps. (Hear hear.) The splendid organization and administration of that body both at home and abroad, and the work they have done, have raised the status of the profession to which we have the honour to belong. It remains for we who have stayed at home to see that that position is maintained in the eyes of the general public. The advance abroad of both preventive and curative medicine has been the admiration of all the other armies. One wonders when one considers the slight mortality of animals in this war. A mortality of a little over 1% in the many thousands of animals carried from over-seas, through U-boat and other risks, and the small total of about 12% through all risks of war, speaks volumes for the good work which has been done by the veterinary profession at the front. (Hear hear.) I am not going to give you a long speech, because I believe that short speeches are the rule at these gatherings; but when you drink this toast I should like you at the same time to drink to the absent members of the Central Veterinary Society who are serving over-seas. Many of them have gained mention; many of them have gained honours. Let us drink their health, and wish them a speedy return to our gatherings. There are several members of the Headquarter Staff here tonight, amongst others Colonel Rainey, who has done a lot of spade work in this war (Applause); and then there is Colonel Aitken. (Applause.) If the Americans were here tonight I think we should be very proud to hear what they have to say of him and his work with the American Veterinary Corps. Then there is Colonel Stordy (Applause), whose name I am going to couple with this toast. I am coupling his name with this toast, because he is Chief Veterinary Officer to the East African Protectorate, and we see and hear so little of our colonial members when they have once gone abroad that I think his being here gives us a fine opportunity to hear the ideas of those over-seas. (Hear hear.) Ladies and gentlemen, I ask you to drink the health of the Navy, the Army, and the Imperial Forces, not forgetting our absent members. (The toast was duly honoured.)

Capt. STORDY: Mr. President, Mr. Willett, Ladies and Gentlemen,

I would in the first place thank you Mr. President and Members of the Central Veterinary Medical Association for the very high honour you have conferred, in entrusting to me the important duty of responding to the toast of the Navy and Army, which Mr. Willett has proposed in such felicitous terms. In the absence of a member of the Senior Service, I would return thanks for the very generous manner in which you have received the toast of the Royal Navy. In the face of an unscrupulous enemy, our gallant sailors have done deeds of heroism, shewn a devotion to duty and performed acts of humanity which command the admiration of the world, and make the British Navy symbolic of all that is powerful, all that is noble, all that is true.

We await, with a hope tinged with anxiety, the decisions of the eminent Statesmen now in solemn conference assembled, and earnestly pray that the high ideals, for which the League of Nations stands, may materialise and be brought within the realm of practical politics. We fervently trust that nothing will be done to impair the supremacy of our Navy—a supremacy which, I submit, Britain has never once abused, a supremacy which has made possible its constant vigil, which has guarded our Homeland, our Empire and the shores of our great Allies, a supremacy which has guaranteed to the world the freedom of the seas.

On behalf of that wonderful Army and its Auxiliaries who have upheld in every sphere of war the best traditions of our race, and have brought the enemy to his knees, I would offer you their most grateful thanks. For tonight, I take it, our thoughts are more concerned with the achievements of that branch of the Service to which so large a number of our professional colleagues belong. As a temporary and humble member of that Organization, I would pay tribute to the great part played by the Royal Army Veterinary Corps in the mitigation of animal suffering, and the prevention and suppression of contagious disease. It stands without parallel in the history of previous wars, and we, as a profession, emerge from this awful conflict of nations with a splendid record of service well done.

For some years I have been in fear and trembling lest the motto emblazoned on the Arms of our College would require to be changed, and sometimes in the night watches I have conjured up visions of "Ora pro nobis" being inscribed thereon. But tonight, I rejoice to feel that a new era has dawned, and that our profession, clothed with a dignity and status hitherto unknown, stands re-born.

We owe, I consider, a very deep debt of gratitude to the Army Veterinary Service, for the position we at present hold. It is a position gained by hard and genuine work—work which has the Government's acknowledgement—which has demonstrated to the British taxpayer our importance from an economic as well as from an Imperial standpoint, and it is work whose eminence has recently received the gracious recognition of His Majesty the King himself.

Within the next few months many of us will have left the regis of the Royal Army Veterinary Corps, and returned to "The daily round the common task," but in whatsoever sphere we may find ourselves, the duty will devolve upon each of us to regard zealously the privileges we have won.

For the profession as a whole, the Council of our Royal College will become the chief custodian of its new found honour and dignity, and I would in all sincerity express the hope that the profession will gather round our worthy President and Council, and give to them its uttermost support. Let us lay aside that lethargy which has so often in the past marked our attitude to all things politic, but which should receive earnest study and

attention, if we are to maintain a high state of efficiency. "Vis unita fortior" graven on our escutcheon—must verily be our watchword, for, combination in these days of progress and change, is the keynote to ultimate success.

Much lies before us to be accomplished, and first and foremost I would wish that the Charters, Acts and Regulations governing our body corporate be carefully scrutinised, with a view to alteration or amendment. I cannot think, for instance, that it can make for good to elect Members to Council for the long period of four years. To become a Councillor is, I trust, the ambition of many members, and the profession should demand ability, zeal and reasonable interest in all matters affecting it, to entitle those who receive that honourable advancement to retain seats at our Council Table.

There are other points demanding careful revision upon which it is not now my intention to dilate; I would, however, ventilate the opinion held by a very great number of members, that the portals leading to our Schools be closed to all save those possessing the higher standard of education; a status worthy of our calling will attract the class of candidate on whom we may rely to uphold the prestige of Veterinary Science.

The success which has attended the labours of the Royal Army Veterinary Corps can be attributed to an admirable organisation, ably administered, executive work of high merit, and last but not least, freedom from lay control. I am, of course, well aware that the conditions which obtain in Civil Communities oftentimes militate against effective veterinary control, but the work of the Royal Army Veterinary Corps indicates what the profession can accomplish when working on its own initiative. It has been stated that, as we come under the classification "Experts," we can never be good administrators. The fallacy of such a statement is exposed when we find experts of the Sister Profession holding sway over Ministries of the Crown, and the past five years of war have shown that in the ranks of the Veterinary Profession we have men well versed in the intricacies of administrative detail.

With bills relating to Public Health and other legislative measures coming before Parliament in the near future, it is time that we bestir ourselves to make certain that the Veterinarian is not submerged, but that we assume our proper place in the advisory and administrative spheres to which we are entitled by reason of our special training.

The Medical Profession has already taken action, and from the *Times* of February 1st, I quote the following:—"There is thus a clear call to each to unite in the common purpose of securing to the Nation the considered and representative judgement of a great profession upon matters on which only this profession is competent to advise."

Surely gentlemen, this clarion call finds an echo in the heart of each one of us. Applied to our own profession never was duty more clearly defined. Let us act in like manner and state our claims. It is certainly time that we shake ourselves free from the trammels of lay control, and until we do so, our position must remain in jeopardy. Take that position in its relation to agriculture; we find that the terms agriculture and veterinary are oftentimes regarded by the public as synonymous, and it behoves us to clear its mind of such an erroneous notion. We are ever ready and willing to work side by side but on an equal footing with agriculture: we have every right to expect—yea demand, that we shall not be placed in subordination to it. The Board of Agriculture of England is a superstructure erected on the foundation of veterinary science—a sure foundation I trow—but do not let us hesitate to build a few stones into that superstructure—corner ones too—so that the public may recognise and appreciate the value and importance of

our position, and mark well the services of those eminent veterinarians who labour within its walls.

I fear I have grievously trespassed upon the privilege you have accorded me tonight, but I would plead as excuse an earnest desire to place before you the views of your professional brethren who labour in other spheres beyond the seas, who have little or no opportunity of stating them, but who look forward to the time when even they may find someone fully qualified to look after their interest in the Council Chamber.

Mr. President, Mr. Willett, Ladies and Gentlemen, I would again thank you for your generous acceptance of the toast to which I have endeavoured to reply. Before sitting down, I would in the name of my fellow colleagues in the Colonies and Dependencies of our great Empire, raise my glass to the success and prosperity of the Central Veterinary Medical Association.

#### "THE PRESIDENT."

Mr. J. W. McINTOSH: Ladies and gentlemen, it gives me great personal pleasure to propose this toast. We have had some very excellent Presidents during the forty five years existence of the Central Veterinary Society, but no President could have thrown more spirit and enthusiasm into the work of the Association than our friend the President this evening (hear hear). The deliberations over which he presided were discharged with a wealth and ripeness of knowledge and with an ease and dignity which is so essential in the qualities of the chair. Professor Wooldridge's activities are not confined to the work of the Association or the work of the profession. I know something of his activities outside these two organisations, and I can assure you that his work in other directions is just as freely given and just as highly esteemed and appreciated (hear, hear). We love him not only for his qualifications of head but for his qualifications of heart as well, a combination which makes him a favourite wherever he goes (hear, hear). Speeches are to be short and I can easily comply with this request as it requires very few words to present this toast, because Professor Wooldridge is well known to all of you. In giving you the toast I should like to associate with it the name of his wife Mrs. Wooldridge (hear, hear). I am quite sure I am uttering the sentiments of every individual in this room when I say that we wish them long life and happiness and all that they deserve—honour, love and troops of friends. (The toast was drunk with acclamation.)

The PRESIDENT: Ladies and gentlemen, will you kindly allow me in the first place to thank you very heartily indeed for the very kind way in which you have accepted the toast proposed so flatteringly by Mr. McIntosh, one of my predecessors in this chair. Please also accept the thanks of my wife. I am very flattered indeed, and very grateful, that you thought to include her in the toast, because I feel sometimes when I am out on what I report to be business, she may have some doubts (laughter). I think after tonight she cannot have any doubt at all that I am engaged on matters of public interest (laughter). I thank you, Mr. McIntosh for having made my peace more beautifully and more plainly than I could have done myself after considerable rehearsals: I have tried often (laughter).

I am very pleased indeed at the good number who have turned up to enjoy the evening along with us. There is a "but," and that is the number of empty chairs which one sees around, owing to influenza and other causes keeping people away at the last minute. There is always a "but" in these things, but one does not want to elaborate that point. We can always find grievances, and that reminds me of an individual who was always finding fault. A particular friend of his was well aware of that, and he said, "Look here, Jack, when you die and when you go to Heaven, if ever you get there, you will

still find fault." "No," said Jack, "surely not." "Yes, you will," said his friend. Subsequently they both died and afterwards met in Heaven. The friend said, "Hallo, Jack, you are here! How are you getting on?" Jack replied, "Pretty well, but—" "Oh," my friend said, "There is a 'but,' is there?" "Yes," Jack said, "My halo does not fit, and my harp is out of tune, and the blessed cloud I am sitting on is damp." I am getting rather into a lighter vein, which one should avoid on an occasion like this, because Mr. McIntosh has given you to understand that I am capable of something sincere. I will try to avoid that kind of thing. Unfortunately, I have to talk too much. I am somewhat in the position of the parrot of which you have probably heard, who was in the habit of imitating his master's whistle. He was kept in an upstairs room, and when he imitated the whistle, the little dog used to come running up to the room expecting to see his master, and when he entered the room the parrot would simply laugh at him. The little dog's tail would go down and he would walk disconsolately away. That sort of thing occurred frequently, but on one occasion the parrot happened to be on a perch and not in the cage. He repeated the offence, and the sagacious little dog, when he got into the room, caught hold of the chain on the perch and pulled the parrot down and gave him a good 'tousling,' and ruffled his feathers rather badly. Presently the poor parrot got back on to his perch, and the mistress of the house, hearing the noise, came up to see what was happening, and was in time to hear the parrot say, "That is the worst of me. I talk too damned much." (Laughter.) I promise you not to offend seriously in that respect to-night, but again I offer you my very sincere thanks for attending here and for having received the toast in the way in which you have.

Before sitting down I think I should extend a welcome to our visitors. I do extend a very hearty and cordial welcome to those who are our visitors to-night. We have with us some very notable representatives of the Royal Army Veterinary Service, whose names have already been mentioned. I do not need to mention their names again. Each and all of them I hope will accept our assurances of the great pleasure which we feel at their presence here to-night—not only the members of the permanent Service, but also those who are members of the temporary services, including Major Sturdy, Captain Fairholme and the other members of the Forces. Then also I would like to take the opportunity of thanking very heartily those of our friends who have entertained us right royally. (Applause.) We have had a real treat from them, and we hope to have more, and it is in order that we may get more that I will sit down at once. Ladies and gentlemen, I thank you very heartily indeed.

#### "THE LADIES."

Mr. F. W. CHAMBERLAIN: The honour has been thrust upon me of proposing what is, I venture to suggest, the toast of the evening. I only wish it were in more worthy hands than mine. Although I cannot do justice to the toast I am second to none in my appreciation of the sex. I am quite at a loss to know what to say. I asked my neighbour if he had any suggestions, and he said "Why, they won the war." I was quite overcome by this brilliant suggestion, with which I quite agree. It was unjust to ask me to propose this toast when there was a neighbour of mine with a sentiment of that description. It is quite unlike the remark I once heard a crusty old bachelor make. He said "In the beginning after man came woman, and she has been after him ever since—an eternal worry, but, by the grace of the Lord, many centuries afterwards, Scotch whisky was invented as a constant solace to man." Now I hasten to say that such a hideous sentiment does

not pervade the mind of any Fellow of the Central Veterinary Society. We are particularly pleased to see the ladies gracing our function. The Central Veterinary Society during the war, thanks to an enthusiastic President and an untiring Secretary (hear hear)—has been carrying on periodical meetings and trying to keep its end up, and it is a particularly happy augury for the future to meet again round a festive board with the ladies around us to give us a send off to better times. I couple with the toast the name of Mrs. Harrison. (The toast was duly honoured.)

Mrs. HARRISON: Mr. President and gentlemen. I must thank Mr. Chamberlain for all the nice things he said about us tonight. I claim that this is the toast of the evening. (Hear hear.) I believe this is the second time that ladies have graced your board. How you gentlemen enjoyed yourselves in the past, really I do not know. We have all enjoyed ourselves very much, and we are looking forward to the next annual meeting in November. You must excuse me for not making a long speech. It is not in my province.

HUGH A. MACCORMACK, Hon. Sec.

#### VETERINARY POLITICS.

Sir,—In reply to Mr. G. Mayall, I wish to state distinctly that I have *not* suggested an attitude of "patience and submission." Nearly all my letter was occupied with pointing out the folly (to use a mild word) of two suggestions put forward at a meeting held to discuss "veterinary politics." Anyone may do that, without incurring an obligation to advance suggestions of his own. I do not ask Mr. Mayall whether he considers the term "ass-like" courteous, or even civil—opinions upon courtesy and civility are so dreadfully divided in our profession.

Mr. Mayall puts a construction of his own upon what other men have written. That sentence I quoted from "Fra Diavolo's" letter does not recommend anything; it simply states an unpalatable truth which too many veterinary surgeons, like Mr. Mayall, persistently refuse to recognise. Perhaps Mr. Mayall sees by this time that the two sentences in which he deals with our alleged indispensability would better have been left unwritten. I notice that he does not touch my point of the long period during which all veterinary practitioners were unqualified; and I may remind him that unqualified veterinary men are much more numerous and skilful now than five years ago.

I agree that we *could* do without insurance fees of 2/6 or 3/6. At the same time I think it useless to demand a minimum fee of 10/6, as many seem inclined to do. A wiser course than either accepting half-crowns or clamouring for half-guineas would be to support the "National" in negotiating for a scale of fees on a percentage basis; and I think that, if the scale published recently by the "National" can be obtained, it will be as much as we can do with regard to insurance fees for the present.—Yours faithfully,

"DAGONET"

#### THE STATUS OF THE VETERINARY PROFESSION.

Sir,—Your correspondent Mr. H. C. Wilkie advances the view that the social status of the veterinary profession is precisely the same as any other profession, and that each individual's social position is only personal to himself. The second proposition is true, but the first most decidedly is not. The mere fact of being a veterinary surgeon is correlated with an atmosphere which society, spelt with a capital S, holds in the greatest disdain. Whereas in the case of the parson, the doctor, the barrister, or the man of letters the preliminary send-off is *typical*

*facto* favourable to his social position, and more especially to that of his womenkind. In the one case the choice of a profession tends to uplift, in the other to drag down. There may be a fair measure of snobbery at the root of this state of affairs, but nevertheless the central fact remains that it exists and is in strong evidence. How many public schoolboys ever dream of becoming veterinary surgeons? And how many veterinary surgeons' sons who have had a public school and a university education can be persuaded to follow the vocation of their fathers? Precious few, and the explanation lies in the circumstances that rightly or wrongly the veterinary calling, as such, is looked upon as a profession of relatively low caste. Viewed from this standpoint it does not appear to have made appreciable progress in the last 100 years, and certainly none at all in the last 40 or 50 years. At all times there have been both gentlemen and veterinary surgeons in the profession, but the veterinary surgeons have not all been gentlemen, and some of the gentlemen have not been veterinary surgeons. If Mr. Wilkie's propaganda work has a reasonable prospect of convincing Society that all veterinary surgeons are gentlemen practising their vocation from purely philanthropic motives a rise in the general scale may in the end obtain. In the meantime unseemly wrangles over a few paltry insurance fees, and rumours in the veterinary press of the formation of trades unions to enforce their payment by the strike weapon, are not calculated to do much toward raising the social status. People are generally judged by the company they keep and the customs they adopt.—I am, Sir, Your obedient servant,

"WATCHMAN."

#### Donation to Royal Veterinary College.

At the April meeting of the Governors of the Royal Veterinary College, London, the Earl of Northbrook in the Chair, the Secretary reported that a donation of one hundred pounds had been made to the funds of the College by the Thoroughbred Breeders' Association. In view of the present unsatisfactory state of the College finances this gift was most welcome, and it was decided that a letter be sent to the Association thanking them for their generous gift.

#### ARMY VETERINARY SERVICE

The King has granted the following authority to wear the Insignia of the Order of the Nile conferred by the Sultan of Egypt in recognition of valuable services rendered.

VOL. XXXI.

## THE SPREAD OF RABIES.

No veterinarian was surprised at the appearance of rabies in the London district last week. Of course it has caused some public panic, and not a few dogs have been, and will be, needlessly destroyed; but there is no mistaking the real gravity of the situation. The Devon-Cornwall outbreak, the more recent Welsh one, this London one, which holds more serious possibilities than either, and the amount of illicit importation and movement of dogs that is known to have taken place, altogether present a distinctly ominous outlook. It is possible that we may have as much rabies in the kingdom this year as we ever had in the nineties. A trying time lies before practitioners, bearing much annoyance but also much serious responsibility. However many genuine cases of rabies occur, there will be many more false alarms; however few, there will still be so much disease in the country that to slight a single symptom that is even suggestive would be criminal.

## FEES IN IRELAND.

A report upon another page shows that the Central V.A. of Ireland is taking a commendable line with regard to this question. A considerable minimum increase in the ordinary fees has been approved, and it is suggested "that the members of the profession resident in the same districts should confer and agree mutually on this point." This encouragement of localised consultation and combination amongst groups of neighbouring practitioners seems the best policy for the societies to adopt, so far as the fees of general practice are concerned. National uniformity of fees is desirable, and may be attained in some special subjects, such as insurance work; but uniformity over the whole range of professional fees presents many difficulties. The variety of conditions in different districts, even sometimes in fairly closely adjoining ones, is very great. The work itself varies greatly; for what is an everyday item in some districts may be so rare as to be practically negligible in others. Other local conditions vary as much; and fees which are quite usual in some districts are almost unobtainable in others. All these difficulties are best met by local arrangements amongst the only men conversant with the details; and just now that seems to be the only effective way of dealing with them. It is also the best step towards a national uniformity, if that is really attainable. Probably no man now has a sufficiently wide knowledge of the subject to warrant a judgment on the latter point; but a good number of local combinations might render such knowledge available.

## THE "ASSISTANCE" OF THE PRESS.

The introduction and spread of rabies in England and Wales has received notice in the public press, mainly in support of the measures of control exercised by the authorities, but a contributor has sent us a copy of a local newspaper containing a column of matter of a quite different character, excerpts from which we print on another page. Fortunately, the mischievous character of the suggestions is lessened by the fact that the journal is a local one, and by the widely spread knowledge of the dread effect of the disease. But the attempt to belittle the skill and integrity of the veterinary officials concerned will find favour with a section of the public; and there are yet many who are unacquainted with the dangers of infection. Liberty of the press is worth preserving: but one can only regret to see it put to ill use by irresponsible persons.

In quite different tone is a short note in the medical column of *The Farmers' Gazette*, Dublin, which we give below:—

"Hydrophobia is such a frightful disease that no steps, be they ever so drastic, are too severe if to prevent it again invading this country. Hydrophobia in a human being is a sight that not every doctor has seen. It has, however, fallen to the lot of the writer to see and attend upon such a case—a horrible and harrowing experience he never wishes to encounter again as long as he lives. He has seen an airman burnt to death in a fallen aeroplane: but the latter sight was as nothing to that of the stricken wretch perishing in the throes of hydrophobia as the result of a bite from a pet retriever.

## Royal College of Veterinary Surgeons.

(Continued from p. 577).

### SPECIAL COMMITTEE ON VETERINARY STAFF.

On the motion of the President, the following report of a meeting of the Special Committee on Veterinary Staff, held on April 11th, was received and adopted:—

*Classification of Veterinary Officers.* The Secretary submitted correspondence showing that the veterinary officers of the D.A.T.I. are not included among the professional officers of the Civil Service, in the same way as veterinary officers of the Board of Agriculture and Fisheries. A draft letter to H.M. Treasury calling attention to this anomaly, and urging its immediate removal, was read and ordered to be sent to the Permanent Under-Secretary of the Treasury.

### PUBLICATION, LIBRARY, AND MUSEUM COMMITTEE.

Dr. SHARE-JONES read the following report of a meeting of the Publication, Library and Museum Committee, held on April 11th:—

**Presentations to Library.** The Secretary reported that since the previous quarterly meeting the following presentations had been made to the Library.

**Annali della Stazione sperimentale per le malattie infettive del Bestiame**, Vol. IV., Fasc. 1 and 2. "Delabere Pritchett Blaine," M.S. Article by Miller Christy. The Spinose Ear Tick, U.S.A. Dept. of Agriculture. Haemorrhagic Septicaemia, H. J. Washburn, U.S.A. Dept. of Agriculture. Preliminary Note on Sheep-Breeding Experiments, E. C. Oliver, L.C.V.D. Report on Experiment of Feeding Bullocks on Turnips and Straw, 1917-18, J. Hendrick and W. J. Profeit.

**Annual Reports:** Imperial Bacteriological Laboratory, Muktesar, 1917-18. Higher Education in State of New York, 1914-15. City of Manchester, Medical Officer of Health. Department of Agriculture, Nyasaland, 1917-18. Notes on Parasitic Mange, County of Lanark Veterinary Inspector.

**Calendars:** Registers of Pharmaceutical Chemists and Chemists and Druggists, 1919.

**Periodicals:** *The Journal of the Board of Agriculture*; *The Journal of D.A.T.I.*; *The Scottish Journal of Agriculture*; *Revue de Pathologie Comparée*; *Journal of Physiology* (per Sir F. Smith); *The Vet. Review*; *The Vet. Journal*; *The Journal of Comp. Path. and Therapeutics*; *The Vet. Record*; *The Vet. News*; *The Rhodesia Agric. Journal*; *New Zealand Journal of Agric.*; *Journal of Department of Agric., Melbourne, Australia*; *Bloodstock Breeders Review*; *British Medical Journal* (per Dr. Bradley); *Educational Times*; *N.Y. University Veterinary Bulletin*; *N.Y.*

**Annual Report.** A draft of the Annual Report was submitted, and after emendations, was approved and ordered to be issued.

**Dr. SHARR-JONES:** With regard to the Annual Report, it is impossible in a document of that kind to give a full account of the immense amount of work which has been done by the various Committees of the Council. That was brought out in discussion at the Committee meeting this morning, particularly with reference to the War Emergency Committee. It is open to any member of Council to amplify in any way he thinks fit the statement with regard to the work of the various Committees. With reference to the War Emergency Committee, Mr. Coleman in particular considered that the immense amount of work which that Committee had done had not received possibly the full amount of credit which it should receive in the Report which you have in your hands, and that he would like to make a personal statement with regard to it this afternoon. In that request I may say that the Committee fully concurred, because I am sure it would be to the benefit of the profession to have a little more information concerning the work of the Committee than can possibly be given in a brief Report of this kind. I move the adoption of the Report.

**Mr. COLEMAN:** I should be pleased to second that. In doing so, I feel in rather an unpleasant position, having at a certain meeting of the Royal Counties Society endorsed the opinion of the general practitioners as to the work of this Council. It had been my intention to bring before the Council to-day the fact that the reports of the various Committees of the Council are so inadequate that they convey to the general body of practitioners a wrong impression of the amount of work that is done. Owing to being on so few Committees, where very little business was done, and that in a very cursory manner, I endorsed the opinion of the Royal Counties Society, but, having discovered my mistake, I admit it. I was present at a meeting of the Parliamentary Committee yesterday while I was waiting for another Committee meeting—I did not join in the discussion—and I found that they did an enormous amount of work on subjects upon which I believe you received a resolution from the Royal Counties Society, which after hearing the discussion I felt was quite un-

necessary. Therefore I want to recall the remarks I made at the Royal Counties meeting, and I wish to ask the Council to support me in the suggestion that the reports should be more copious in the future, in order that the main body of practitioners may have a better and fuller report of the work that is done by the College. I should like now, if I may, to refer to the work that the War Emergency Committee has done for the Royal Army Veterinary Corps. I should like to read a motion that I brought before the Council last July to the following effect:—“(1) That the Army Council be respectfully asked (a) To consider the grave necessity of compensation upon ceasing their military duty being granted to veterinary officers who had practices prior to the war, especially those of the Territorial Force who were mobilised and had no time to arrange for the carrying on of their practices during their absence. (b) To revoke paragraph 2 (j) of Army Order No. 406 of 1915, as this is a grave injustice to Territorial Officers. (2) That the Parliamentary Committee appointed for the purpose be advised of the anomalies affecting the promotion of Temporary Officers A.V.C. and those of the A.V.C. (T.F.)” The cursory remarks that are made in the Report do not give the members of the Army Veterinary Corps any knowledge of what has been done by the Committee. I should like to draw your attention to the fact that Article 497 of the Royal Warrant for Pay, under which most of the Territorial officers joined, says: “Officers employed under the conditions of Article 496 shall, provided that they serve for the full period of their engagement or of the emergency in respect of which they were employed (unless a shorter period is specially approved by our Army Council) be entitled on the cessation of such employment to a gratuity at certain rates.” I will only speak about myself and not refer to other people, although there are a number of them in the same boat. When I resigned I applied for my gratuity, and I was told that it was not issuable. I then got my solicitor to make enquiries, and he found there is an Army Order, 406, of November, 1915, paragraph (j) of which applies to my particular case. It says: “The gratuity is not issuable to officers (j) who voluntarily resign their commissions or voluntarily revert to unemployment before the expiration of the period of emergency.” Army Council Instruction 1360 of 1918 gives some of the gratuities admissible under Article 497 of the Pay Warrant: “It is notified that in the event of an officer being allowed to be demobilised or to revert to unemployment at his own request in anticipation of general demobilisation, any gratuity under Article 497 of the Pay Warrant to which he is otherwise entitled up to the date of release will not be withheld by reason of his having asked to go. Paragraph 2 (j) of Army Order 406 of 1915 will not be held to apply to such cases. This Army Council Instruction is no authority for any application for early release from the army being made. It deals solely with the gratuity aspect of the case.” The point I wish to make is that the Army Council have been doing most strenuous work during the war and we can quite understand that such a small body of men as the Army Veterinary Corps has been overlooked in regard to this little matter, but I assume—I lay stress on the word “assume”—that by some means or other the steps that we have adopted here in this Council have come to their notice, that they have recognised the injustice of Army Order 406, and have revoked it by the issue of Army Council Instruction 1360 of 1918. I should like, if it is possible, to ask this Council respectfully to approach the Army Council and ask whether they cannot make it retrospective.

**The PRESIDENT:** I do not think that that is altogether in order, but I fully appreciate what you have said. You are speaking on the Report?

**Mr. COLEMAN:** I am amplifying the Report.

The PRESIDENT: I think you know as well as everybody else that the Annual Report is merely a record of actual work done put in the briefest possible way. We should all very much like to have the Report greatly amplified for the sake of the profession, but at the present time it is not advisable to go too much into detail. The expense of printing is simply awful.

Mr. COLEMAN: I think the profession ought to be properly informed as to what we do, and not be under the impression that we do nothing.

Mr. TRIGGER: I do not think it is sufficiently realised by the profession that, although this Council only meets on Friday afternoon, the whole of the previous day, from 11 o'clock in the morning until 5 or 6 o'clock in the afternoon, is devoted to Committee work, and also the whole of the time on Friday morning from 11 o'clock until lunch. When the members of Council come to London they have no chance of a "joy ride" of any sort; they have to work for the whole of two days. I do not think that is sufficiently realised by the profession.

Dr. SHARE-JONES: I should like to say, in reply to Mr. Coleman, that the specific statement is made in the Report that the Committee has dealt with the question of the pay and promotion of officers of the Royal Army Veterinary Corps. That results have followed, from whatever source they have emanated, speaks for itself, and I am very glad that Mr. Coleman has amplified the Report in the way he has done.

The motion for the adoption of the report was put and carried unanimously.

#### ELECTION OF EXAMINERS.

The PRESIDENT: We will now proceed to the election of Examiners, and here I have to announce that all the elections today are for the period of one year only.

The following gentlemen were elected:—

#### MEMBERSHIP EXAMINATION.

**Class D. Veterinary Medicine:** N. Almond, F.R.C.V.S.,  
F. L. Gooch, F.R.C.V.S.

**Veterinary Surgery:** R. J. Hickes, F.R.C.V.S.,  
Major W. S. Mulvey, F.R.C.V.S.

**Class C. Pathology:** H. Caulton Reeks, F.R.C.V.S.,  
W. Jackson Young, F.R.C.V.S., D.V.S.M.

**Materia Medica:** Hugh Begg, F.R.C.V.S.,  
Major J. Peddie, F.R.C.V.S.

**Veterinary Hygiene:** H. Taylor, F.R.C.V.S.,  
W. Woods, F.R.C.V.S.

**Class B. Anatomy:** H. G. Bowes, F.R.C.V.S.,  
W. E. Ison, F.R.C.V.S.

**Histology and Physiology:** W. Legge Symes, M.R.C.S.,  
F. W. Lamb, M.D.

**Stable Management, &c.:** H. J. Dawes, F.R.C.V.S.,  
Major A. B. Mattinson, M.C., F.R.C.V.S.

**Class A. Anatomy:** B. H. Mellon, Capt. A.V.C.,  
F.R.C.V.S., M.R.C.S., L.R.C.P., D.P.H.,  
H. L. Roberts, F.R.C.V.S.

**Chemistry and Physics:** J. M. H. Munro, D.Sc.,  
M.R.C.S., L.R.C.P., F.I.C.

**Biology:** W. B. Bottomley, Ph.D., M.A., F.L.S., F.C.S.

#### FELLOWSHIP EXAMINATION (Old Regulations).

**Veterinary Medicine and Surgery:**

Prof. J. Macqueen, F.R.C.V.S.,  
**Veterinary Hygiene and Sanitary Science:**

Wm. Woods, F.R.C.V.S.,  
**Pathology and Bacteriology:** J. Malcolm, F.R.C.V.S.

It was necessary for a ballot to be taken only in regard to the Examiners for Pathology and Materia Medica in Class C, in the former of which Dr. E. J. McWeeney had made application in addition to Messrs. Reeks and Young, and in the latter of which Mr. E. C. Winter had made application in addition to Messrs. Begg and Peddie.

The PRESIDENT announced that a letter had been received from Dr. McWeeney saying that, although his health had greatly improved, it had not done so to such an extent as to allow of his giving an absolute undertaking to attend at all the centres, but if re-elected he would serve the College to the best of his ability.

**Illness of Mr. Bloye.** The PRESIDENT: I should like to bring to the notice of the Council the illness of one of our late Examiners, whose name would have been on the list had he been in good health; I refer to Mr. Harvey Bloye. I suggest that we might send him a vote of sympathy.

Mr. MULVEY: I beg to propose that.

Major ABSON seconded the resolution, and it was unanimously agreed that such a letter should be sent.

**Appointment of Scrutineers.** On the motion of Mr. McKinna, seconded by Major General Thomson, it was, in accordance with custom, left in the hands of the President to appoint the scrutineers for the election of Council.

The PRESIDENT: That concludes our business, and I thank you very much for your attendance here to-day.

Mr. LAWSON: I should like to move a hearty vote of thanks to our President for taking the Chair.

Mr. TRIGGER: I second that.

Mr. MULVEY: I desire to support it. There are very few men who recognise the immense amount of work, the large number of hours and days, that our President devotes to this Council; I wish it were more widely known.

Mr. SUMNER: All the members of the Council fully appreciate it. Our President comes all the way from Windermere at the bidding of the Council more times in the course of the year than I dare to suggest, and the debt the profession owes to him is one it can never repay.

Mr. TRIGGER: I should like very heartily to support the motion. Never in the history of the Council has a President devoted so much time to the carrying out of his duties as Mr. Garnett has done since he has occupied the Presidential Chair.

Mr. COLEMAN: All the members of the Council are perfectly aware of the immense amount of time that Mr. Garnett devotes to the work of the College. He has been a whole-time officer ever since he was elected.

The resolution of thanks was carried by acclamation.

The PRESIDENT: Thank you very much, Gentlemen, for all the kind things you have said about me.

The meeting then terminated.

#### SOME OBSERVATIONS ON EQUINE INFLUENZA.\*

By G. P. MALE, M.R.C.V.S., Reading.

For some time I have been under a promise to your worthy and persistent Secretary to contribute something for discussion at your meetings, and I make no apology for choosing this subject, for I feel that there are so many points which still need elucidating in connection with it. It is only by discussing these things and comparing notes that we can hope to solve them. Also, with influenza affecting so many of the human race, it behoves us to consider whether there is any connection between it as it affects horses and man. As the two diseases resemble each other so closely the experience gained with animals may possibly be of some assistance to our human *confrères*, who up to the present appear to have no definite knowledge of either the cause, mode of infection, contributing causes, or treatment of the disease.

I do not propose to enumerate the symptoms or to

\* Read at the meeting of the Central Veterinary Society, London, on Thursday, April 3rd.

go into all the aspects of this disease, as the former are so well known to you all and time would not permit; but there are certain questions which I ask you to consider:—

1. The cause. 2. What is the relationship between so-called influenza and contagious pneumonia? 3. Is the pneumonia a secondary infection or a primary disease? 4. What conditions predispose towards it? 5. What is the incubation period? 6. How is the disease contracted? 7. How long can an animal be infective? 8. What methods of treatment are most successful? 9. Is there any known method of inoculation which can be recommended as a preventive or curative. 10. Is there any evidence pointing to contagion or infection from animals to man or *vice versa*?

The term influenza has been used in a very wide sense to include almost any catarrhal inflammation of the mucous membranes accompanied by fever, but I think it should be restricted to those cases which have what to my mind are characteristic symptoms, namely, the marked infection and often discolouration of the conjunctiva of the eye, accompanied by a high temperature, great depression, and oedematous swellings of the skin. The disease also is very contagious, and this should confirm any doubt that might arise as to its diagnosis. The old term "pink-eye" expressed the condition very aptly.

As we all know, the disease varies greatly in intensity, and, as in the human subject, some outbreaks are comparatively mild; in others the whole of the organs of the body—lungs, liver, kidneys, etc., are congested, the heart much depressed, bowels torpid, and often pneumonia or pleuro-pneumonia supervenes.

I do not refer in these remarks to the condition called catarrhal fever, or horse-dealers' fever, which I look upon as a separate disease due to the streptococcus of strangles; and should not be confounded with influenza.

*Cause.* A good deal of experimental work has been carried out with a view to finding the cause of the condition, and I think there is little doubt that it is due to an ultra-visible organism which is able to penetrate the closest filters and cannot be demonstrated.

The disease has been transmitted from horse to horse by injections of filtered blood, also by intravenous and subcutaneous injections of warm blood, and even semen from affected animals.

One experimenter was able to transmit the disease from experimentally infected animals to others, but in no case was he able to isolate micro-organisms from the blood or blood serum which proved virulent on inoculation.

In those cases where pneumonia has been a marked feature several organisms have been discovered.

Schütz and others have described a streptococcus which appears to resemble the streptococcus of strangles.

Lignières found a bacillus, the *pasteurella equi*, a variety of the bacillus *bipolaris septicus* of the haemorrhagic septicaemia.

Col. Watkins-Pitchford who carried out an investigation on contagious pneumonia, described a small bacillus which he found in the diseased tissues of the lungs and also in the blood. He was not able to classify it exactly, but possibly it corresponds with that noticed by Lignières.

Hutyra sums up the position when he says "For none of these organisms has sufficient proof been advanced that they can produce the disease primarily, and no one has ever succeeded in producing croupous pneumonia in its typical course artificially. It is therefore possible that the primary cause of the disease, or the infective agent which transmits the disease from animal to animal, is a micro-organism which is not yet known,

and that the streptococci as well as the ovoid bacteria which are normal habitants of the healthy air passages exert their pathogenic action only after the specific virus has already affected the animal, and they then subsequently produce the inflammatory changes attributed to them."

That is to say, the primary infection and the general febrile condition so weaken the natural defences of the body that the secondary organisms are able to exert their specific pathogenic effect. Watkins-Pitchford, although describing an organism frequently present, does not preclude the possibility of an ultra-microscopic organism in conjunction with it.

One's own observations of the disease bear out this idea, and I notice that human pathologists are also inclined to this view. In the human subject it was at one time supposed to be due to Pfeiffer's bacillus, but very probably it will be found, as with the organisms discovered in equine cases, that this is a secondary infection, and that the real cause is an invisible organism.

Some authorities hold the view that there are two distinct diseases—*influenza*, and *contagious pneumonia*, and that they are not related; but those who have closely watched an outbreak in a large number of animals will have noticed that some show characteristic signs of *influenza* without pneumonia, others have pneumonia in the later stages of *influenza*, while others again show pneumonia early in the course of the disease. Many of you will have attended large numbers of army horses in the first years of the war, and will have noticed this variation.

In a large thoroughbred stud that I attended every variety of the disease was shown. The first case was one of pleurisy in a foal about 3-4 months old that had arrived from Newmarket with its dam, about 3 weeks previously. On July 15th it was found to be ill, with high temperature, injected membranes, and great depression. The respirations became difficult, and on July 22nd I performed paracentesis thoracis, and removed ten measured pints of sero-fibrinous liquid from the left side of the chest. On July 23rd I removed eight pints of similar exudate, to the great relief of the foal. On July 25th breathing was much improved, but there was a large swelling on the side of the chest. I lanced this in several places, and a quantity of serous liquid oozed away. The foal made a good recovery, and by Aug. 7th was full of life and spirits, and subsequently has been raced.

No other cases developed until Aug. 17th, when the dam became ill with all the symptoms of a severe attack of "pink-eye," but she was convalescent by Aug. 28th.

On Sept. 21st a cart horse in an adjoining stable died rather suddenly. The cause of death was acute pneumonia, and it appeared that it had been unwell for some days but had been kept at work until the day preceding death.

The next case was in Nov. when pneumonia supervened on influenza in a thoroughbred mare, but she made a good recovery.

In Dec. a stallion became affected with pleuro pneumonia and purpura complications following on the usual symptoms of influenza. This horse also recovered.

A spell of most severe weather then came on which necessitated the animals being kept in their boxes which were rather small, with the result that the disease spread rapidly, virulence increased so that a large number of the mares who were then heavy in foal became affected, and many of them had pneumonia. Nearly all the young stock yearlings fell ill, but with these the disease was not nearly so severe. They had a high temperature, injected membranes, depression, swellings of the legs etc., but none of them had pneumonia. The early cases were of course strictly isolated, and the weather being fine the animals were kept out in the open as much as

possible; except the cart horses and stallion which were among the first to be affected.

I quote this outbreak as it showed all forms of the disease and it gives some indication of the period of incubation.

**Period of Incubation.** About three weeks elapsed between the first few cases, and also from the time the first foal arrived on the stud until it became affected.

In other outbreaks I have noticed a shorter period. A mare that brought the disease to one stud came from Ireland, and it was about nine days before any distinct symptoms developed. Some authorities state definitely that the period of incubation is from 4 to 6 days. When artificially inoculated the period varies from  $3\frac{1}{2}$  to 10 days. In infection following coitus 6 to 9 days.

In experiments made by Gaffky on pneumonia cases the period of natural infection was from 20 to 44 days, and in different outbreaks he noted there was a certain regularity about the time. It appears that the incubation period is variable, and I would suggest that in these delayed cases the organism, although living in the air passages, does not produce definite symptoms possibly for some considerable time, until a chill or over-exertion, etc., gives it an opportunity to develop; or the animal may be so resistant and the disease so slight that the symptoms are not noticed for some time. It would seem then that in order to prevent a stud being infected from foreign mares, it is not sufficient to isolate them for a few days. At least 3 weeks should be allowed before one can say they are safe.

**Method of Infection.** There is some doubt as to the method of infection. Experimentally it can be transmitted by intravenous and subcutaneous inoculation. In the natural way infection probably takes place by ingestion, inhalation, and also sometimes during coitus when the semen contains the organism. Some animals are much more susceptible than others, and some have great powers of resistance although constantly exposed to infection. I have noticed when animals are kept in different parts of a stud, perhaps 3 or 4 in each field, how one animal from this field and one from another field some distance away will fall. This can only be explained by admitting transmission by the atmosphere, which some authorities dispute.

Some observers claim that cohabitation is the only natural mode of infection, while others, for example Watkins-Pitchford, state that in his experiments he was unable to transmit pneumonia in this way. If the latter is correct it is obvious that the predisposing causes necessary for infection were absent, or that the animals used had obtained some immunity from a previous attack. Possibly they had sustained a slight attack of influenza and recovered, and consequently would not be susceptible to infection with the secondary organisms which appear to cause the pneumonia symptoms.

**Predisposing Causes.** Anything which weakens the defences of the body will predispose to the disease. It has been my experience that nearly all bad outbreaks have occurred during a long spell of severe weather, either cold or continuous wet, and no doubt that would reduce the vitality of the individual, as would depressingly hot or muggy weather. Over exertion or work of any sort will predispose to lung complications. So important do I consider this that in any outbreak in working horses I have the temperature taken once or twice daily; and when at the beginning of the war horses were taken from civilian stables, exposed to wet and cold or herded together in sheds without adequate food, every horse had his temperature taken daily, and if raised at all he was not put to work. By this means many fatal cases were prevented. If an animal worked with a high temperature pneumonia nearly always resulted. Overcrowding is one of the most fruitful predisposing causes of influenza. In an outbreak where

the horses were housed in open sheds close together, I had them turned loose in a field with surprisingly successful results.

Horses kept in badly ventilated stables quickly succumb. An open shed, a yard without covering even, if the animal is well rugged up, is preferable. Catarrhal affections predispose. Want of exercise is I believe a contributing cause especially among cart horses, the legs quickly become filled, the circulation congested, and when infection is present the animal will not be in such a fit state to resist it.

Pregnancy is another condition which favours the disease, and abortion is frequent in affected mares. In this connection it is interesting to note that the foals born at full time when their dams were badly affected usually lived. They were very icteric at first, and weaker than usual, but they quickly recovered, and did not contract the disease *ex utero*.

Animals between 3 and 8 years old appeared to be more susceptible than older or younger ones.

It may be said then that it is a disease of over crowding, and bad hygienic conditions.

As to the length of time an animal can be infective, cases are on record where stallions have been able to transmit the disease by coitus for months, and even one to two years, but this is of course exceptional.

Animals that have apparently recovered may be carriers for a considerable period, especially if they have suffered from the pneumonic form, and probably this is due to diseased foci being left in the lung.

In two outbreaks among thoroughbreds during the foaling period, although the mares were served from three to six weeks after convalescence the stallions did not contract this disease, and there was no evidence of a spread of infection by this means. The mares also showed no tendency to become barren, most of them were quickly got in foal. The risk, therefore, of infection from mares cannot be very great.

#### TREATMENT.

I do not propose to weary you with details of treatment, but I think most practitioners are agreed that good hygienic conditions are a *sine qua non*. A big box where the animal can walk about, with a half door which should always be open, are essential. If the atmosphere is humid and close the doors and windows should be wide open. The next most important point is a free action of the bowels. In this condition the bowels are very torpid and the liver congested, so that saline aperients and calomel are necessary, except in those cases where there is some enteritis.

The heart being greatly depressed needs stimulation to assist it to relieve the congestion in the various organs, and no drug has been so successful in my hands as hypodermic injections of strychnine several times daily. Medicine can be given in the form of electuary, but on no account should drenches be administered, and in bad cases even balls upset the animal. Stimulation of the chest walls has had marked results in some cases; the temperature has fallen, the animal left off grunting and the respirations improved. It increases the activity of the skin, and immediately relieves the congested heart.

Medicated inhalations of steam give relief in some animals, and oxygen is strongly to be recommended, given every two or three hours for 20 to 30 minutes, where pneumonia is a complication.

I have used nuclein in these cases, also various sera and vaccines, but I cannot honestly say that the results have been better with them than without. A vaccine is strongly recommended by some practitioners as a preventive and curative, but it is difficult to judge, unless it is used very extensively under various conditions, whether it is effective or not.

In one case where it was used at the request of the owner's veterinary surgeon on a particular mare, this animal was the only one on that farm which became infected, although large doses were given on several occasions. I would like to hear the opinion of members on this point.

Major Chambers has published results of treatment with formalin and creasote injected intra-tracheally 2 or 3 times daily. He advises 10 c.c. of a 10% sol. of formalin or 10 c.c. of the following mixture:—Creasote 1 part, 63% alcohol 10 parts. The latter mixture he prefers to the former, as the inflammation at the seat of injection is less, and it can be used more often. He claims that the mortality was greatly reduced by this injection.

Salvarsan and neosalvarsan have been used a good deal on the Continent, especially in Germany, but the reports from different sources appear to be somewhat conflicting, so that it cannot by any means be looked upon as a specific. There is some difficulty in its preparation, it must be injected intravenously, and some animals do not tolerate the drug at all well.

Quinine, antipyrin, antifebrine, aspirin, potassium iodide, etc. are commonly used, especially in the human subject, but personally they have been quite ineffective in my hands, in fact I am of opinion they are contraindicated, as they exert a too depressing effect on the heart. I prefer digitalis, strophanthus, caffeine, or ammonia compounds.

Major Newsom has used large doses of iodine; 1 drachm in bolus twice daily, and considers this method more successful than any other.

Various sera have been prepared, and some have been used on a large scale, especially the anti-streptococcus serum polyvalent, and it is possible this may have some effect in some outbreaks, but as the specific organism has not yet been cultivated, we cannot hope at present to get either a preventive or curative agent.

Immunization with serum from horses which had shortly before recovered from the pectoral form have also not given uniform results. Outbreaks vary so in virulence that what appears to be a specific in one outbreak may entirely fail in another.

As to my last point—Is there any connection between human and equine influenza? As far as I know this has never been suggested by any writers on the subject, but why I cannot say, seeing that the two diseases as they affect horses and man are almost identical. They are both very sudden in their onset, very contagious, and affect chiefly the respiratory tract.

A high temperature, great depression, congestion of the capillary vessels, disturbances of the liver and torpidity of the bowels are marked symptoms. In both the predisposing causes are identical. In both pneumonia is a frequent complication. In both the causal organism is very difficult to define, and all the signs point to an ultra-microscopic organism.

In both the disease varies greatly in virulence at different periods. Sometimes the cases are sporadic, at other times they take the form of an epizootic, and large numbers of animals and men are affected.

My thoughts were directed to the possible connection between the diseases by the fact that in nearly every outbreak in animals I was myself attacked. Medical men in charge of units where disease was rife on several occasions told me that the men in charge of the horses were going down with influenza, and as fresh batches of men nursed the animals so they were affected themselves. No doubt predisposing causes would be necessary, as in animals, to make them more susceptible, but where these causes were present the men certainly were very commonly affected. I do not suggest that humans often contract the disease from animals, but it does seem to me very probable that when men are put under certain conditions in which their vitality is lowered they become susceptible to the disease.

I should very much like to hear the experiences of members on this point and the others which I have very briefly and inadequately tried to introduce to your notice for discussion.

In most diseases, for example, tuberculosis, glanders, etc., it has taken many years of investigation to prove infection from animals to man or *vice versa* and I think research is needed also in this disease before one can say dogmatically that there can be no relationship. I hope that research may be forthcoming, and trust the Veterinarian will bear his share.

#### CENTRAL VETERINARY ASSOCIATION OF IRELAND.

(NATIONAL V.M.A.—IRISH BRANCH).

A meeting was held on the 24th Jan. at the Limerick Junction Hotel. The President, Mr. B. P. J. Mahony in the chair; other members present Messrs. M. J. Cleary, Mullingar; P. J. Howard, Ennis; L. P. Power, Cahel; T. R. Mulcahy, Clonmel; J. J. Condon, Tipperary; A. J. Macdonald, Kildorrey; and Capt. E. C. Winter, Hon. Sec.

The Hon. Sec. read the minutes of the last meeting, held at Turners Hotel, Cork, on the 7th July 1914, and explained that his absence on service, and the conditions existing owing to the war prevented his calling a meeting before. The president stated that no apology was necessary under the circumstances, and doubted if a meeting could have been got together in any case.

The minutes were approved, and signed by the president. Apologies were received from Mr. J. F. Healy, Hon. Treas., (whose car broke down on the road), Messrs. P. W. Creagh, A. Dobbin, J. W. Nolans, Prof. Craig, and Capts. P. D. Reavy and A. J. Moffett.

Votes of condolence were passed with Mr. Jas. Preston, on the loss of his son, a promising member of the profession, and with Messrs. A. J. Murphey and Capt. Moffett, who had both lost their wives recently, and the secretary was instructed to convey the resolutions to the members concerned.

The outgoing officers were unanimously elected to carry on the business of the association for the coming year.

The matter of finance was then gone into, and it was decided not to ask for any subscriptions for the years 1914, 15, 16 and 17 as the affairs of the association were suspended for that time, no meetings had been held and no expenses incurred.

Re outstanding subscriptions, the secretary was asked to again circularise the defaulting members, and to put in execution a resolution passed in October 1913, to make any member over three years in arrear to be a defaulter and to remove his name from the list of members.

The Secretary asked for, and was granted unanimously, some discretionary powers with regard to this resolution, after pointing out that, in his opinion, lapses in this matter were due more to carelessness than anything else, and the members present promised to help in collecting arrears and bringing in stray sheep to the fold.

The question of holding the meetings in places of easy access to the majority of the members was discussed at length, and it was decided to hold the next meeting at the Limerick Junction on the 30th April, at 1.30 p.m., and to let the July fixture stand over till the next meeting so as to be able to take the wishes of the other members into consideration.

A Committee of five was elected to carry on the work of the association for the year, consisting of:—Messrs. Mahony, Winter, Healy, Howard, and Cleary.

The consideration of the following resolutions forwarded by the Hon. Sec. of the Veterinary Medical Association of Ireland was then taken up:—

"We urge upon the Council of the Royal College of Veterinary Surgeons and the National Veterinary Association, that in regard to any proposed legislation relative to a Ministry of Health, the utmost vigilance be observed to ensure the establishment of a Veterinary Intelligence Section in connection therewith."

"That the profession cause action to be taken to have Veterinary Officers attached to each Rural District Council, to advise on matters relating to diseases communicable from animals to man, in somewhat analogous terms to the Medical Officer of Health."

Capt. WINTER proposed that the first resolution be formally endorsed by this meeting.

Mr. CLEARY: If that resolution takes effect, what will be our status?

Mr. HOWARD: The only thing you can do, if a Ministry of Health is established, is to urge on the Council of the Royal College of Veterinary Surgeons to see that a Veterinary Officer is appointed on the board set up by the Ministry, in the same way as Medical Officers were included in the Local Government Board in this country; and I notice that it is not intended to include Ireland in the jurisdiction of the proposed Ministry of Health. You may have seen in the press that the question was recently discussed by the Local Government Board and some of the members were of opinion that the functions of the Ministry of Health will be extended to this country.

The PRESIDENT: I think we should do all we can to have this bill extended to include Ireland.

The HON. SEC.: I think this resolution ought to be sent to the Local Government Board.

Mr. HOWARD: The Local Government Board may say that they are entitled to administer any such Act, and the Department of Agriculture may contend that they are entitled to act in the matter.

Mr. CLEARY: The Department of Agriculture offered fifty pounds a year to work Veterinary Dispensaries in this country, but no man could possibly do the work at that price.

Mr. MAHONY: It was absolutely impossible to do it at the figure offered, and in some districts five hundred would not pay a man for doing it.

Both resolutions were adopted.

Mr. MULCAHY: I notice by the press that in England the various Associations have considered it advisable to raise the professional fees charged, and I think we ought to do the same. The cost of living, travelling, wages and drugs have undergone a very considerable increase since the war started.

After a lengthy discussion, in which all the members present took part, it was decided that the ordinary fees should be raised by, at least, 50%, and it was suggested that the members of the profession resident in the same districts should confer and agree mutually on this point.

The Secretary was instructed to notify the press of this resolution.

#### SOME AMERICAN EXPERIENCES.

By Capt. E. C. WINTER.

Gentlemen,—I must first congratulate you all on our once more coming together after the stress and strain of the last four years, and express the pleasure it gives me personally to be once more amongst you, and to see our worthy Chairman in the seat of honour. I regret our friend, Jack Healy, has been prevented by a motor accident from joining us. I want also to remind you in his absence, that no society can get along without the sinews of war. Our subscription is a small one, and I think it is in most instances only cussed carelessness

that prevents it being paid. We have already overdrawn our account with the Hon. Treasurer, and that should not be. Please pay up now. Our last meeting was held at Turner's Hotel, Cork, on the 7th July, 1914, and a good deal of water has flowed under the bridges since, and a great many good fellows have "gone west," more's the pity; but we hope they have not died in vain, and amongst the number were a good many members of our profession, which profession has "done its bit" and received proper recognition for it too, from the authorities. I hope that, later on, some of the men who have served on the various fronts in the many theatres of war will come forward and give us of their experiences. It is only at meetings such as this that we can interchange ideas, and profit personally and professionally by so doing. I find after a generation's experience, that I have myself a lot to learn.

We meet diseases abroad that we never meet at home, and we meet others that are familiar and easily dealt with, which become under war conditions veritable scourges, and decimate the ranks and render the animals affected a drag on mobile forces. Wherever you get large numbers of animals together, under often very adverse conditions, you get disease rampant, even though those animals are not doing any work, as in remount depôts. How much more does this apply when the animals in question are asked to work hard on short rations, in all weathers, on all sorts of roads, and with all sorts of drivers. In those cases minor ailments, which at home are hardly worth thinking about, such as cracked heels, collar galls, saddle galls, catarrh, etc., make all the difference between the animal being a useful servant and a useless incumbrance. The question of skin disease also is a matter for anxiety, as well as a thousand and one other little things. In all those cases a little "horse sense" combined with veterinary skill works wonders. Now to the subject of my text.

After doing remount work in Limerick from the outbreak of the war, I was asked to take service with the British Remount Commission in Canada, and having accepted the offer I set sail from Tilbury Dock on the 19th Nov., 1914, on the good ship "Minnehaha" of the Atlantic Transport line, on which I had the good fortune to meet several old friends, including Capt. P. D. Reavy, of ours, and we had a very pleasant trip over. By the way, the "Minnehaha" made twenty-six trips unconvoyed, and was sunk on her twenty-seventh when protected. She had in the meantime several narrow escapes, and on one or two occasions gave a very good account of herself.

At New York we all got orders to proceed to Montreal for instructions, but had time for a bird's-eye view of that great city on Sunday, the 29th, on the evening of which day we became acquainted with the mysteries of the "Pullman car." I must say I like the British sleeping car better, unless one can afford the luxury of a drawing room or "compartment." The arrangements for dressing and the accommodation for smokers, in a land where almost everyone smokes, leaves much to be desired.

The one thing that impresses every Britisher first is the size of the country; one has to travel a couple of thousand miles to know what it means. The next thing that strikes one is the enormous waste of everything, and the untidiness, and next to that comes the universal "hustling." We here might with advantage adopt a little of that hustle, and I think that an ideal citizen might be found in a blend of the Yankee, the plodding Anglo-Saxon, the canny Scot, and the impulsive Irishman. In fact, the average American is a blend of many nationalities, and the only true American left is the Indian, who has adopted a good many of the bad points of civilisation, and left out the good ones.

The American characteristic *par excellence* is that of

"getting there" when he sets out, and letting nothing stop him. However, sad to relate, a great many "get there" only to find that they have suffered so much in health, owing to the nervous strain, that they are unable to enjoy the fruits of their efforts. "Quick lunches," and very often, no lunch at all, do not help one along a thorny road.

To return to the question of the supply of horses, and those much maligned animals the mules; the most amazing feature was, to us, the apparently unlimited supply of good, sharp, well bred, active gunners, with size, bone, and action, that turned up day after day and month after month at the dealers' shows. The supply of heavy draught horses and mules never ran short either, but the cavalry horse as we know him does not exist in anything like large numbers. Most of the horses of this type that were shown to us were of the "Standard" breed, and too long in the leg and too light in the barrel for our requirements, although they were not lacking in stamina or speed; in fact some of the so called "cow ponies" would give points to the best of ours in those particulars. The horse *par excellence* of the American continent now is the light draught horse or "gunner." Fortunately for the breeders of these animals, and for the British tax payer, the war came at a time when there was a slump in the horse trade in America.

The cavalry horse is rapidly vanishing from the American continent, owing to the development of motors, and the ban on racing in many of the States. It behoves the Government here to do something to encourage light horse breeding before it is too late, if the cavalry horse is not to become a thing of the past, and it seems to be the opinion of those best qualified to judge that this arm of the service is still indispensable.

The principal diseases for which we had to reject horses were wind, eye, and traumatic affections, but their feet were as a rule good, and about fifty per cent of those shown were innocent of shoes till they were purchased. As they were bought, the horses were shipped to concentration depots, and when possible they were held there for a month or six weeks before final shipment, it being found that a great many of them contracted disease during their passage through dealers' yards and livery stables, as well as from unclean cars on the railroads. The cars over there, as here, are all supposed to be thoroughly cleaned and disinfected, but this is nearly always done in a perfunctory manner, just as it is here.

Strange to say, skin disease was not prevalent, and mange was conspicuous by its absence. I don't think I saw more than four or five cases of actual mange in the thousands of horses I handled; ringworm was prevalent and became troublesome if not actively dealt with.

When one considers all the horses had to go through in the way of knocking about, the long railroad journeys,—often from one end of the continent to the other, and the unclean places they often had to be put in, one can only wonder at the excellent results obtained on the whole. Of course individual treatment was often out of the question, and skilled horsemen were conspicuous by their absence.

I shall describe later on some of the more common affections we were called on to treat, and meantime I shall say a few words about our friend the mule, that animal "without pride of ancestry, or hope of posterity," which does most of the hard work in the U.S.A. and lives on the hardest fare. It is said over there, and with some justice too, "that it takes a nigger to manage a mule," and the combination certainly seems to work well. There is no doubt that this animal likes to be made much of, and that he will do almost anything for one who understands how to manage him—he will be led but he won't be driven. I will back a team of good

mules to do 50% more work than a team of horses, and to live and thrive on 75% of the food. The Missouri mule is a very fine animal, and often grows to a great size without being leggy; a 17 hands mule is not uncommon, and he will weigh almost as much as a horse of the same height. Most of the mules bred in the States are raised in the Middle West, and the same applies to the horses of the light draught type.

Train loads of horses used to number on an average about 500, say twenty-five cars of 20 each in the case of riders or mules, and about 17 or 18 to the car of heavy draught horses. The average car is 36 feet long, but a good many of them run to 40, and 8 feet wide. Thirty-six hours is the limit allowed by law for horses or other stock to run without food or water, and that only under a special contract, the usual time being 24 hours; with a minimum stop over of five hours. It is wiser to allow twelve hours stop over if at all practicable, for it takes horses an hour or two to settle down and rest, and they begin to feed again after a lapse of four or five hours; one can then easier spot any that are off their feed or going sick. I also think 24 hours is quite long enough for a run—as that generally means 30 hours without food or water—it takes a couple of hours generally to load and cut out sick, and roughly about an hour to unload. In bad weather or in case of a break-down the limit must of necessity be exceeded, as it is not every station that has accommodation for large numbers of stock.

Where possible, it is always wiser to take temperatures before loading, as horses will be apparently in good health and frisky with a high temperature, and it is dangerous in the extreme to ship anything with a temperature of over 102. Such cases may return to normal in a few hours without developing any disease, but, on the other hand, if they are shipped may develop anything, and be very ill on arrival at their destination, or perhaps dead.

Now as to the diseases that gave us most trouble. The most common affection was what was called "shipping fever," which really meant that the animal had a rise of temperature and was ill, and might develop any one of a dozen diseases later on.

Some of the wisacres over there, who called themselves scientists, invented a cure and preventive, in the shape of a serum, which was prepared and administered under conditions which would shock anyone with any pretensions to scientific training. The losses directly attributable to the use of this nostrum sounded its death knell, but not before a few people made money out of it, and a few others lost a small fortune.

People who dealt in horses were at their wits end to combat this so-called "disease," and entirely overlooked the fact that care in selection, and a little nursing and individual attention, were all that was required in a great many cases. A careful man going through the stock every day and all day and spotting the animals off colour was worth all the nostrums put together.

Septic pneumonia was a common result of the strain put on the stock, and here again "horse sense," coupled with fresh air and nursing, worked wonders. Everything was tried from tapping the chest and sinapisms to patent preparations warranted to cure all the affections horse flesh is heir to, and it was found that letting them alone and supplying fresh air, even to the extent of turning the horses out in the open in the coldest weather, was the most effective treatment, coupled with the use of salines and green food, when available.

Strangles was a common disorder, but except where purpura developed was easily dealt with. Purpura was rather common where the depots were situated on marshy or very foul ground, as a good many of them were, owing to railroad facilities and other reasons.

Glanders, for a while, gave a good deal of trouble, and

it was found necessary to test all our stock at intervals. Parke Davis ophthalmic disc proved the most effective and easiest mode of testing, but in the later days of the commission, the intra-palpebral hypodermic method was used altogether. In the case of a doubtful re-actor the ordinary hypodermic test was used for confirmation, but in dealing with large numbers of horses or mules that was too troublesome in the first instance. Either of the eye tests required nothing more in the way of inspection afterwards than running the horses through a chute and looking at the eyes, and no previous taking of temperature was necessary. The "Complement fixation" test I look on as the last word in testing, and it was always employed in doubtful cases before destroying an animal.

Mules are not very responsive to any of the tests, even the latter one, and great care had to be exercised in handling those refractory animals and in weeding out the affected. They always got an increased dose of the serum, both in the case of the hypodermic and intra-palpebral tests.

Twenty four hours was generally long enough for the application of the eye tests, but it was always wiser to look them over at the end of forty eight hours, as some cases showed up then. I have here a couple of typical photographs of re-actors to the eye tests.

Some of the States insist on all animals of the equine tribe being tested before they are allowed to enter, or travel, while others do not worry. It would be far better if there was a federal law to equalise these regulations and deal with all the States alike, as it would prevent one State sending contagion into another by various routes. This is where our insular position helps us in combating contagious diseases.

Gangrenous Dermatitis was for a while a great pest in some of our depots, and if not detected early gave a great deal of trouble and caused a great deal of loss. The first thing noticed was that a horse was slightly lame, and very soon—if not promptly treated, became very lame, and the disease was gone so far that a cure was almost impossible. In deep ground a slight lameness might escape a not very keen observer and the disease meantime was making progress and the contagion spreading.

On washing off the feet and legs a nasty sore was found round the coronet or higher up the pastern or leg, or perhaps two or more such sores were found. The wounds looked unhealthy and there was a nasty ichorous discharge, and possibly a slough or two. If allowed to go on the trouble spread to the deeper structures and caused the death of the patient. Foul ground, contaminated by animal excrement, contributed largely to the spread of this affection, and on its appearing in a corral it was always advisable to have the horses removed to clean dry ground. The treatment eventually adopted for affected cases was to wash thoroughly with petrol, remove any dead tissue, and dress with a strong caustic, thereafter treating as a simple wound with dry dressings. The in-contact horses should all be walked through a bath containing a solution of cupri sulph. or some such preparation, and the feet and legs examined every day. Quicklime on the floors of any standings also acted as a preventive. I have seen as many as 500 horses affected with this fell disease in the early days out there, and the life of the V.S. in charge was not exactly a bed of roses. Those horse had at this time to be treated in the open, on deep ground in bad weather. Later, smaller depots were the rule, and it was possible to get all sick animals under cover. This disease seems to correspond with an affection called over there "Summer sores"—with this difference, that "Summer sores" may affect any part of the body. In either case the bacillus necrosis does not seem to enter the unbroken skin, and a wound or bruise is necessary beforehand.

Fistulous withers was not at all uncommon, and gave a great deal of trouble from time to time. All sorts of treatment were tried; finally it was decided to give it best, and dispose of any affected animals as soon as noticed. The origin of this affection is still in obscurity, and the theory of its being due to a wound or bruise is not always tenable. I think there is something in the theory propounded in one of the veterinary journals recently, that it is due to filaria, and the subject is worth investigating. The affection is very prevalent in the States, even in horses that have never been worked or housed.

Lice, in the spring-time were very prevalent, and it was almost impossible to give the horses proper grooming, owing to the cost of labour and the shortage of anything like grooms. Most of our labour was, to say the least of it, unskilled.

Ringworm if not seen early and checked gave a lot of trouble too, but, strange to say, mange was not prevalent, although the U.S.A. got the credit of sending the disease to France—to my mind, undeservedly. A very good line of treatment for all skin affections was the sulphur vapour baths just being tried when I left the States.

Fractures and traumatic affections generally were not so common as one might expect, considering the large numbers of animals handled. This immunity was due in a great measure to the fact that all horses were unshod behind. I have yet to meet a broken leg or very serious injury caused by a kick from an unshod horse.

Parturition cases were common at certain periods of the year, and a very large number of the mares were in foal. Often a foal was slipped in the railroad cars or the corrals and it was not easy to find the mother. Those cases as a rule gave very little trouble, and the mare, if found, was all right and ready to go on in a day or two. Some of the foals were reared but proved a financial failure.

I have touched on only a few points I would like to elaborate, but I am afraid I have already exhausted your patience. I would have liked to tell you of the country and its grandeur and vastness, of its yet undeveloped resources, of the splendour of the Rockies, of which I saw a good deal, of the verdure-clad hills of Virginia, the blue-grass region of Kentucky, and its caves, the rolling wheat and corn belts of the west, the alfalfa fields, the sugar and cotton and tobacco plantations, with their indispensable "coons." Also of the up-to-date cities, which often spring up in what to our ideas is a marvellously short space of time.

I had the pleasure of going through some of the veterinary colleges out there, and attending some of the meetings of the veterinary associations, and I can honestly say that with all their up-to-dateness, and all their push and go, they have nothing on us over here; quite the reverse in fact. The American practitioner is, as a rule, far behind the Britisher, and the Canadian is worse. They have a few stars in the States, but the average practitioner is far behind ours, and a great many of them do little more than inoculate hogs against hog cholera. Their colleges are not as well equipped or staffed as ours either.

I thank you gentlemen for having given this rather disjointed paper such a patient hearing, and I hope by our next meeting, to be able to induce some of our members who have served in France to give us of their experiences there.

Mr. MARONY: Gentlemen, you are after hearing a very elaborate paper read by Capt. Winter, whom we all congratulate on his return after his very strenuous and exacting duties in America; and we are all glad to see him so hale and hearty, and hope he will continue so for many years to come. I am sure it was a very great strain on Capt. Winter to leave home and family to

undertake a very trying business in America, but, like a great many others, he answered the call of duty, and we are pleased to see him back again. Many others who answered that call were destined never to return. Personally I am very proud of the part played by the profession in this war. The members of the profession discharged their duty well in alleviating the sufferings of the dumb animals committed to their charge. Further, I am glad that their services have been recognised by the State and that a great many honours have been bestowed on them. I hope that like Capt. Winter others of them will come forward when they return and give us the benefit of their experience while abroad. I also think the time has come, with the conclusion of the war, when our profession should receive from the State that recognition which is its due; it rests with ourselves to raise the standard of the profession, and I trust we will all endeavour to do that, by individual and collective effort.

I notice that Capt. Winter has made no mention of cases of lockjaw amongst his patients, now you know that in this country we get a great many cases of lockjaw, possibly in America the microbe is rare. [Capt. Winter: Quite the reverse.]

The PRESIDENT: Let me say that the paper is interesting and instructive, and I hope it will be spoken to by the members present.

Mr. HOWARD agreed with what the President had said, and commented on the rarity of mange amongst the American horses. He further stated that the Army horses were the most fruitful source of mange in this country. He asked if Capt. Winter knew if the disc had been tried in testing for tuberculosis. He was surprised to hear that there was not more success in the use of the serum for shipping fever. He was also pleased to hear that in spite of Yankee bluff we can still more than hold our own against them.

Mr. POWER agreed with the essayist in the efficacy of fresh air and cleanliness in the treatment of pneumonia and allied affections. He did not agree with Mr. Howard's remarks about the Army and mange; he lived a long way from a military barracks and yet he got plenty of mange cases.

Mr. CONDON endorsed Mr. Power's remarks *re* mange, and agreed also with the remarks made about pneumonia, but remarked that early on in France they had not much time to treat horses.

Mr. CLEARY: Capt. Winter does not give us much idea of the prevalence of disease in the States in which he travelled, and he seems to convey the idea that a large percentage of the contagious diseases broke out in the depots. It would be well to know if veterinary surgeons in the districts from which the horses came found instances of those diseases. It would be very strange if they did not.

Mr. HOWARD: It is well known that when horses are herded together, as they were at the beginning of the war, disease breaks out amongst them. I remember in the Limerick depot 30% of the horses present were sick from one thing or another.

The PRESIDENT: There are instances where horses from infected districts convey disease when huddled together with others.

Mr. CLEARY: But the disease must have been there all the time.

Mr. MULCAHY spoke again on the army being a source of mange in the country and gave instances to support his assertion.

Capt. WINTER: There seems to me to be one or two slight misconceptions about my paper which I wish to clear up. I never meant to say that I saw no tetanus in the States; what I said was that I never saw a case of tetanus follow dermatitis; there is tetanus to be seen, but we saw very little of it. Also it was impossible for

us to tell if there was disease in the districts from which horses came. The country is a very big one, and some of the stock we bought came thousands of miles to the sales yards. Mange does exist, and in some districts is prevalent even amongst the cattle, and there are government dipping stations for them, but my remarks applied more to the animals we had to handle. Most of the stock we bought came off farms and all were supposed to have been worked, we bought no range stock if we could avoid it. Those seasoned horses rarely took sick, the "green" ones were what gave the trouble. I would like to ask Mr. Cleary if he ever saw 5000 horses together. I have seen 20,000 in one depot.

The tuberculin test is largely used in cattle in the States and Canada, but the eye test does not work so well in the cow as it does in the horse. The intradermal test is often used in the case of cows, with good results.

The question of the prevalence of mange, or otherwise, in army horses I am not at liberty to discuss further, but I have, like some of the other members here, seen a lot of mange in this country that could not be traced to army horses; it is a good deal more common than is supposed, and a great many carriers and disseminators of the disease are never suspected of being affected at all.

The one disease that worries the farmers in the States is "hog cholera" and in spite of millions of inoculations every year it is still rampant.

I had the pleasure of going through Parke Davis & Co's works and farm, when passing Detroit, Michigan, and the place well repays a visit. Things in the drug way are done on a very large scale, and the utmost care and supervision are used to procure purity and exactitude in all their preparations. A very large staff of analytical chemists is kept for testing the materials used, as well as the finished products; anything that is not up to standard is thrown away at once.

I must apologise for the incompleteness of this paper, there are many things omitted that I would like to have included, but time would not permit. I have tried to give you my impressions of some of the things I have seen and experienced, and I can only conclude by saying that I am very glad to be back again where I belong.

## VETERINARY POLITICS.

Under the pseudonym of a well known and eminent journalist "Dagonet" is pleased to launch a scathing criticism on the proceedings of the Eastern Counties and Central Veterinary Societies. The former for trying to put pressure on the Insurance Cos. to increase their scale of fees. In these days of increased cost of living enhanced value of animals, therefore necessarily increased premiums, it is surely only reasonable to ask that the professional fees, which I submit are meagre in the extreme, should be raised. In other words this Society is trying to better the profession which "Dagonet" is pessimistic enough to think can be done without. Then he joins issue with the "Central" more especially in regard to District Representation. I quote his words "The system of Societies running candidates for the Council has given us many mediocrities and some non-entities." This statement has I think gone farther than any that has yet appeared, for there have been very few changes on the Council during the last 10 years, therefore the mediocrities and nonentities must still remain. How grateful the Council would be to "Dagonet" if he would forward his name.

I, as one of the candidates mentioned in his letter, may be misguided in my efforts to stir up the lethargy in which the profession has sunk, but so long as I feel that my endeavours are earnest and that they are used for the furtherance of our honourable profession, so long

shall I continue my present course. No apologies are needed for either Society, we will let the profession as a whole judge them.

April 17.

J. WILLETT

I have read with some amusement "Dagonet's" letter, in your issue of April 5th in which he challenges the collective wisdom of the Eastern Counties and Central Veterinary Societies. What a pity such a display of criticism should be lost under a *nom-de-plume*. I would suggest that the most convincing proof of the writers wisdom, would be to withdraw from cover and fire his "gas" shell from open ground, then the profession would be in a position to relegate to its proper place that intelligence he claims, and the position he occupies in the scientific and social worlds—a position with which he appears to be quite satisfied.

I do not think that either of the Societies referred to will object to criticism—in fact we welcome it, and so far as I am personally concerned, that was my object. It was no part of my object to elaborate "points of remedy." I made suggestions and I am quite willing to take the collective voice of my professional brethren. Unless "Dagonet" is prepared to own to his utterances then I think he had better remain in obscurity for ever.

#### ORDER.

RUSSIAN TROOPS IN NORTHERN DISTRICT.

No. 88.

22nd March, 1919.

Archangel.

In reward for special services in the strife against the enemies of Russia in the Northern District, for distinguished service in the field, and for services connected with the re-organisation of the Russian Army—by virtue of the authority vested in me by the Provisional Government, I award the following:—

ORDER OF ST. STANISLAV, 2nd Class with Swords.

Major F. CHAMBERS, O.B.E., R.A.V.C.

Capt. G. BAENETT, M.C., R.A.V.C.

ORDER OF ST. STANISLAV, 3rd Class with Swords.

Lieut. J. McALLAN, R.A.V.C.

#### ELECTION ADDRESS.

To the Members of the

Royal College of Veterinary Surgeons.

Gentlemen,

I have been nominated for re-election to the Council of the Royal College of Veterinary Surgeons, where I have served for the last twenty years, and I venture to ask my friends to return me once more. My attendance at the Committee and Council Meetings during the last four years will, I think, show that I have the best interests of the profession at heart, and the necessary time to devote to its service. I have served on the Registration, Parliamentary, Honours and Prizes, and Finance Committees, and I can assure you that I take my duties seriously; and if you do me the honour to return me to the Council at the forthcoming election, my time and services will be given to your interests as freely and devotedly in the future as in the past.

Yours faithfully,

ALEXANDER LAWSON.

Manchester, April, 1919.

#### The "Assistance" of the Press.

The following extracts are from a column in *The Express and Echo*, Exeter, under the headlines "Is it Rabies?" "Opinions of a Famous Expert." It is difficult to see what useful purpose can be served by the publication of an individual "opinion" which traverses the experience of many men who have made disease the study of their lives. Yet, since D.O.R.A. has ceased

from troubling, any remonstrance by the authorities would probably be labelled "interference with the liberty of the subject."

"A few days ago, I called on probably one of the best known 'doggie' men in the world. As a judge, exhibitor and breeder of fox terriers, Mr. Vicary's name is known in every civilised country on earth. He says: 'I am not at all satisfied that they have proved a single case of rabies.'"

He told me that he had only once in his long experience seen one case of indisputable rabies, and that was a hound in Devon some years ago, when the trouble was stamped out by destroying the whole pack.

"Nobody seems to understand what originates the disease in the first place, but we do know that if one mad dog bites any other animal the terrible disease is passed on. The first case is notified, let us say at Plymouth. The next is discovered at Exeter, I merely take these towns as examples. Now, the mad dog in Plymouth obviously could not have bitten the dog in Exeter, could he?"

"We have had it reported that a large number of human beings have been bitten by dogs declared to be mad. Are they a penny the worse for it? Not in one single case. Now, I know, of course that they have received the Pasteur treatment, but I am not convinced. I do not remember a cure for anything else which is so unfailing."

"The methods employed to determine cases, are in my opinion very curious. When a suspected case is reported they destroy the dog. If I were responsible I should lock the suspected animal in some perfectly safe place and keep it under observation. If he had rabies he would soon die. He would be unable to take his food, as in this disease there is a constriction of the throat which makes it impossible for the dog to swallow

If the animal is able to eat and drink easily that is proof that there is no rabies."

"Some long time ago I had a dog which had all the symptoms of madness. Any of the inspectors would have declared it a case of rabies. They would have been wrong. It was merely a case of distemper which, in this instance, affected the brain."

"What is it the matter with these dogs? In my opinion they have epilepsy brought on by the rubbish sold as substitute dog foods during the war. I do not consider there has been one single case of rabies."

#### Importation of Dogs from France.

In a written answer to Major Glyn, Mr. Churchill says that owing to the importation of rabies into this country through dogs brought from France, it became necessary to forbid officers and men to bring back their dogs with them.

To allow dogs to be brought home, the Army Council accepted the generous offer of the Royal Society for the Prevention of Cruelty to Animals to defray the cost of maintenance for the six months' quarantine required by the Importation of Dogs Order, 1914, of 500 dogs at a time at the quarantine station at Hackbridge, which has been approved by the Board of Agriculture.

Under the arrangements which have been made, the dogs are collected in batches in France, and, when passed free from symptoms of contagious disease by an officer of the Royal Army Veterinary Corps, are sent by special arrangements to Hackbridge. During March over 100 dogs have arrived at the kennels there. Dogs may also be brought over direct by private arrangements between the owner and the Board of Agriculture and Fisheries, but this, of course, entails expense to the owner.

MAY 3, 1919.

VOL. XXXI.

## SCHEDULED DISEASE.

Practically a third of 1919 is now over, and we can form some idea of the start we are making in our post-war campaign against scheduled disease. The outlook is threatening, and will be so for a long time; but our position is as good as could fairly have been expected.

The most serious figures are those of rabies and foot-and-mouth disease. It may be that we are hardly beyond the beginning of our troubles with rabies; but those troubles would not have arisen if British subjects had not broken the law. If to the 55 cases returned this year up to date are added the 104 at the latter part of last year, we get a truer idea of the extent of the mischief. The Board would have kept rabies out of the Kingdom if their regulations had been obeyed; and will stamp it out in time if they are given a fair chance.

The number of outbreaks of foot-and-mouth disease this year shows that it is still a serious danger; but the total of animals involved is fortunately relatively small.

Swine fever shows a distinct increase upon last year, but is still far below the figures of 1917, which in turn do not approach those of 1916. Possibly the history of the disease during these later years may suggest to the Board some new regulations.

Parasitic mange continues to rise; but so far this year the figures do not show anything like the increase indicated in the corresponding period last year, so we may hope that we are in sight of regaining control over it.

The three remaining diseases—anthrax, glanders, and sheep-scab, have all declined more or less. In the case of sheep-scab the decrease from last year's figures is only slight, but those for anthrax show a much greater drop.

One notable feature in the returns is the small amount of glanders. There was reason to fear an increase this year; but so far there have been fewer cases than any previous year has shown in the corresponding period. Glanders, from its course and nature, is a risky subject for prophecy; but our present outlook upon it is about as helpful as it well could be.

The Board have now entered upon a distinctly difficult period. A good start has been made; but the general co-operation of practitioners is essential. There is always more danger of contagious disease at the close of a great war, and an isolated case of carelessness might have serious consequences.

## MALIGNANT ŒDEMA IN SHEEP AND PIGS.

Oppermann, in 1913, published a lengthy article upon this subject. He commences by recalling the fact that malignant œdema complicates, by preference, wounds of the skin and mucous membranes which are necrotic, which bleed little, and the edges of which after a short time close and become scabbed, thus impeding the access of air—that is, of oxygen, which is the chief bactericide against anaerobic germs. The practically constant presence of the specific microbe of malignant œdema in most solid materials which come into contact with the animal body, the superficial earth, air, litter, instruments of grooming and of shearing, walls of stables, fences, more or less dirty hands and clothing of attendants, etc., make it possible for the disease to appear upon all farms. Moreover, it is now known that the receptivity of the animals of the farm is general; the horse, rabbit, pigeon, guinea-pig, and mouse may all be naturally infected, and nearly always succumb to the disease. The reason why malignant œdema is not observed daily is that usually phagocytosis is so active in the parts inoculated that the spores introduced into the tissues are unable to develop to bacilli. This phagocytosis may be counteracted or annihilated by the accidental presence of other germs, such as staphylococci, the bacillus prodigiosus, etc.; in these cases, the disease generally follows its normal course. It is also known that, whenever the tissues are infiltrated, severely contused, or necrosed, the spores of malignant œdema may evolve to the bacterial form without needing the co-operation of microbes neutralising phagocytosis.

In *sheep*, malignant œdema is a mortal affection. The author names four principal accidental causes, namely:—parturition, castration, shearing, and bites of dogs.

Malignant œdema following parturition, also called "pseudo-charbon post-partum," is comparatively frequent. In the space of five years, the author observed it in 22 flocks; on one occasion, 46 ewes died in a flock of 350 head. The disease begins in the vagina or in the neighbourhood of the vulva; from thence the characteristic swelling extends upon the buttocks, into the perineum, and even affects the udder. The prognosis is unfavourable.

As therapeutic treatment, the author advises multiple scarifications, followed by the pressing out of the infiltrating liquid and the injection of a 2% potassium permanganate solution or a peroxide of hydrogen solution, at the periphery of the swelling. This should be done at the very commencement of the disease, and even then it very rarely succeeds.

Prophylaxis is therefore preferable; and the author gives careful directions for this, which may be summarised as follows. He attends carefully to the litter, and immediately removes the whole of the after-birth. He very carefully disinfects the genitals, buttocks, and perineum a short time before parturition; and, immediately after it, he annoints the vulvar mucous membrane with an ointment containing 2% of potassium permanganate. If special lambing premises are available, only the ewes ready to lamb are brought there, after previous disinfection of the genital organs and their immediate neighbourhood. If no such premises are available, a portion of the sheep-fold is taken for the purpose, and fenced in by a double row of hurdles. Its surface of dung, etc., is removed, the new surface is sprinkled with a disinfectant, then covered with a layer of turf, and finally with soft clean straw. Soft straw is preferable to stiff coarse straw, as the latter may injure the lips of the vulva, which are always slightly swollen after parturition. Clean straw always contains fewer malignant oedema spores than that which has moulded, which is more or less in putrefaction. The author emphasises the danger from any use of the leaves, etc., of beets, which are usually soiled with earth, and much contaminated by the malignant oedema microbe.

Castration, which the shepherds usually practise without the least antiseptic precaution, is often accompanied by a direct inoculation of the spores of malignant oedema. From a prophylactic point of view it is important to operate as aseptically as possible in the first place, and afterwards, as an open wound remains, to avoid subsequent inoculation. For the latter object, the same precautions as are taken in lambing suffice.

Shearing by means of shears exposes the animal to the risk of multiple wounds of various depth. Infection may be direct, or follow subsequently from contact with the litter or any other inert spore-bearing substances. Immediate disinfection of all wounds is indicated; but it is better to avoid wounds by the use of special shearing machines.

Dog-bites may cause direct infection of the wounds they produce. The saliva of the dogs may be virulent, especially when they have fed upon the flesh of sheep dead of malignant oedema. Wool, which is deeply introduced into the wound at the moment of biting, may also be infective. The remedies are self-indicative. Dogs given to biting are got rid of or rendered unable to bite; and if, despite these precautions, a bite is found, it is surgically treated.

*Malignant oedema of the pig* is sometimes observed after castration, or after the injection of serum against swine erysipelas. Here also the sole preventive remedy is the disinfection of the site of inoculation. As in ordinary practice it is impossible to carry out such disinfection efficaciously when inoculating against swine erysipelas, a certain percentage of accidents due to malignant oedema must always be reckoned upon.—(*Annales de Médecine Vétérinaire*).

W. R. C.

#### VETERINARY TOXICOLOGY.

The following notes, extracted from the Annual Report for 1917, of Dr. J. F. Tocher, Analyst to the Highland and Agricultural Society of Scotland, are of interest.

The contents of the fourth stomach of a bullock were examined, because the bullock was one of those which became ill suddenly and died within twenty-four hours. The *post-mortem* examination showed intense inflammation of the stomach, but no active poisons were found in the stomach contents which, however, were otherwise abnormal in respect that a large quantity of sand was found to be present. In the absence of other evidence, it was concluded that the bullock had died from some cause associated with the presence of so much foreign and mechanically hurtful material.

*Ewes and dried grains.* Several valuable ewes, nursing big healthy lambs, died within forty-eight hours after having been shifted from a field where they had been grazing for some time, to another field where they were fed with dried grains and cake, in addition to grass. The stomachs and intestines of some of these ewes were examined for arsenic, lead, and alkaloidal poisons, with negative results. The contents of the various stomachs were found to have a distinctly acid re-action, the acid amounting to 2.5 per cent. expressed as lactic acid.

The mixture of dried grains and undecorticated cake used was sent in for analysis, and was found to possess a high degree of acidity, as much as 3.2 per cent of lactic acid was found to be present; other acids being also present in minute quantities. The acidity of the grains was due to the action of lactic fermenting organisms upon the sugars normally present in this particular feeding stuff. Whether the fermentation was promoted by the presence of cotton cake or not is a matter for further investigation.

The effect of such normal bacterial action and resulting acidity in the digestive tract of sheep is a problem for the veterinary physiologist to consider, but it is easy to see that the normal activities of the stomachs of sheep would be suspended, and that death would result simply from impaction, or in other ways. In any case, it was reported that acidity and abnormal bacterial action in the feeding stuffs were considered to be the most probable cause of death; but that the facts should be placed before veterinary experts for their consideration and final judgment.

*Pigs—Phosphorus poisoning.* A member sent in several samples of pigs' stomachs for analysis. Phosphorus was found to be present both in the stomach and bowels of the pigs. Phosphorus is the chief constituent of a well-known rat poison, and phosphor paste left carelessly about a farm steading is the only way phosphorus in any form could be reasonably supposed to reach a piggery.

*Fowls—Spotted Liver.* Fowl poisoning was suspected by a member, who sent in several fowls for examination. No poisonous substances were found in the alimentary canals of these animals.

The liver, however, was found to be in a diseased condition, being riddled by multiplication of the parasite *Coccidium avium*. The disease is popularly known as "spotted liver," and was undoubtedly the cause of death in this case.

*Water.* A sample of water was analysed for poisons, and was found to contain metallic lead. It was therefore the cause of death of two ewes which had been drinking the water.

#### GENERAL REMARKS ON TOXICOLOGY.

The sender of the above notes is of opinion that there is a considerable number of cases of suspected poisoning in animals sent to analysts, where it would be advisable to have the active co-operation of the analyst with a veterinary surgeon.

Periodically, analysts should be invited to attend meetings—social and business—of veterinarians, and to read papers on interesting cases. We as a profession have held ourselves apart from other scientific workers much too long, and we have lost considerably by so doing. It cannot be expected that a toxicologist or analyst can possess the amount of knowledge of pathology of the average veterinary surgeon. The writer has seldom lost an opportunity of getting in touch with analysts on the subject of poisons, water and milk analysis, and the adulteration of foods, and has gained—and given, much help by the active co-operation. Agricultural societies would be well advised to appoint veterinary surgeons to collaborate with their analysts in suspected cases of poisoning in live-stock.

F.R.C.V.S.

#### VICTORIA VETERINARY BENEVOLENT FUND

A quarterly meeting of the Council of the Fund was held at the Registered Offices, 10 Red Lion Square, London, on Thursday, April 10th, when there were present: S. H. Slocock, President, in the chair, Messrs. Banham, Garnett, Gooch, Kelland, McCall, Sumner, Trigger, West, Willett, Wooldridge.

Apologies for absence were received from Messrs. Dawes, Johnstone, McGuinness, McIntosh, Price, and Young.

The Minutes of the previous meeting were taken as read and confirmed.

#### SECRETARY'S REPORT.

The Secretary submitted the following report, which was received and adopted:—

Since the previous quarterly meeting the following donations and new subscriptions have been received:—

##### Donations:—

D. Marshall, Capt.	£2 2 0
G. Garnett	10 6
H. Taylor	10 6
J. Buxton	7 6

##### Collecting Bares

J. Martin	1 0 0
A. Renfrew	10 6
Proceeds of Entertainment arranged by Mr. A. Renfrew, of Broadway	33 4 6
Bolton's Cinema	15 15 0

##### Life Membership Subscriptions:—

G. F. Banham	10 10 0
Norman Brear, Capt.	10 10 0
F. W. Willett	10 10 0

##### New Subscriptions:—

T. Bannatyne, Capt.	£1 1 0
Hugh Begg	10 6
W. J. Dale, Lt.-Col.	10 6
T. J. Davis, Major	1 1 0
W. B. Edwards, Lt.-Col.	5 5 0
J. Ewing Johnstone	1 1 0
E. C. Lloyd	10 6
J. McCunn, Capt.	1 1 0
T. McGuinness	1 1 0
E. B. Reynolds, Major	1 1 0
S. Smith (in memory of his father)	2 2 0
J. H. Thomson, Major	1 1 0
R. C. Trigger	2 2 0
E. Wallace, Capt.	1 1 0
A. J. Williams, Col.	10 6

Mr. A. Renfrew of Broadway, Worcestershire, very kindly undertook to arrange an Entertainment, the proceeds of which were to go to the Fund. Mr. Renfrew has forwarded a cheque for £33 4s. 6d., and the thanks of the Council are due to him for this very practical way of showing his sympathy with the Fund.

The sum of £5,000 received from the Stephenson Bequest has been invested in accordance with instructions, in the purchase of 6% War Loan, 1929-47, and the nominal amount purchased is £5252 9s. 6d.

The Securities registered in the names of the Trustees have now been transferred to the name of the Association. A separate Donations account has been opened at the Bank into which all donations are entered. The Bank has agreed to pay interest on the amounts standing to the credit of this account.

*Investments.* The Hon. Treasurer was authorised to invest part of the balance of Donations, 1918, in the purchase of £200 Consols.

*Life Members.* It was unanimously resolved That the following be elected Life Members of the Fund:—Messrs G. F. Banham, J. Hammond, A. Renfrew and F. W. Willett.

*Relief.* No. 18, Mrs. T. Correspondence was submitted as to the circumstances of this recipient, and it was resolved That the grant of 10/- weekly be discontinued at the end of the present month.

No. 33, Miss W. An application was again submitted from Miss W. and the Secretary reported the result of enquiries made. It was resolved That a grant of 10/- weekly be made, to commence as from April 1st, 1919.

No. 35 Mrs. M. Correspondence was submitted, and the Secretary was instructed to supply a form on which proper application may be made.

No. 44, Mrs. F. An application was submitted, together with replies to enquiries made by the Secretary. It was resolved That in the opinion of the Council there is no immediate necessity for relief in this case.

*Accounts.* Accounts were submitted and approved and ordered for payment.

This concluded the business of the meeting.

#### VICTORIA VETERINARY BENEVOLENT FUND (INCORPORATED)

The first general meeting of the members of the Victoria Veterinary Benevolent Fund since its incorporation was held at the Registered Offices, 10 Red Lion Square, London, W.C., on Thursday, April 10th, 1919, when the following were present:—Mr. S. H. Slocock, (President) in the Chair, Messrs. G. A. Banham, F. W. Garnett, S. H. Gaiger, J. C. Coleman, Col. J. W. Brittlebank, A. Lawson, J. McI. McCall, F. L. Gooch, H. A. MacCormack, H. Sumner, F. G. Samson, E. A. West, J. Willett, G. H. Wooldridge, P. J. L. Kelland, Hon. Sec. and Treasurer, and F. Bullock, Secretary.

*Minutes.* The minutes of the annual meeting held on June 5th, 1918, were taken as read and confirmed.

**Election of President.** On the proposition of Mr. Sumner, seconded by Mr. West, it was unanimously resolved: That Mr. S. H. Slocock be re-elected President for the ensuing year.

Mr. Slocock, in thanking the members for his re-election, said that he was a little diffident at taking the position again. He did so, however, because, having been connected with the Fund a little while, and now that we were entering upon a very much improved position as an incorporated Fund, he would like to remain another year until the work was completed. Then he hoped that some fresh blood might be infused into the post, so that the Fund should have a fresh start and be made into a Fund of which we might all be proud. In the meantime he promised to do his best to promote the interests of the Fund.

**Vice Presidents.** The PRESIDENT explained that under the new constitution the gentlemen who acted as Trustees of the Fund had gone out of office, and he suggested that it would be an honour to the Fund if they would accept the position of Vice-President. They were Mr. F. W. Garnett, Sir Stewart Stockman and Mr. W. F. Barrett. To these he suggested the name of Mr. E. A. West, one of the retiring Vice-Presidents, to whom the Fund owed the very substantial financial assistance received so regularly from the Boltons Cinema.

On being put to the meeting, the Vice-Presidents as named were unanimously elected.

**Hon. Secretary and Treasurer.** On the proposition of Mr. Gooch, seconded by Mr. Banham, it was unanimously resolved: That Mr. P. J. L. Kelland be re-elected Honorary Secretary and Treasurer of the Fund.

Mr. KELLAND in replying, said that he appreciated very much the honour of being elected once again to the position. His feeling in the matter was that he was simply in the hands of the Council. He would very much rather if someone else would take up the work who would be able to do more good for the Fund.

**Auditors.** It was resolved on the proposition of the President, that Messrs. Woodhouse and Wilkinson be elected Auditors of the Fund, at an honorarium of six guineas per annum, and that they be thanked for so generously consenting to act for so nominal a fee.

#### ANNUAL REPORT AND BALANCE SHEET.

The PRESIDENT in submitting the Annual Report and Balance Sheet, said that it was hardly necessary for him to add any words to introduce it. The Fund had now become incorporated, having received a most munificent legacy from the late Dr. Stephenson, and we were now in a position, or would soon be, to do a good work amongst the necessitous and deserving dependents of our professional brethren. He invited discussion or remarks from those present.

Mr. GARNETT suggested that it was now time for the Council to consider whether they could not increase the amount of some of the grants above the ordinary maximum of 10/- per week. He thought that in view of present high prices, this might be done in some of the cases, and of course each case should be considered on its merits.

It was decided that the matter should be referred to the Council.

Mr. WILLETT said that it was evident that the Fund had done very good work. One of the best, to his mind, was that they had done what they could in one or two instances to setting up a boy in life, and helping him to get a good start. The money voted in such cases was, he thought, put to excellent use.

Mr. WEST moved the adoption of the Report, Mr. Banham seconded, and on being put to the meeting it was unanimously carried.

**Stephenson Bequest.** Mr. THATCHER, Solicitor, explained the situation with regard to the residue of the

Stephenson Bequest, and stated that as soon as a decision had been reached with regard to the interpretation of one of the clauses of the will the residue of the estate would be distributed.

**Balance Sheet.** On the proposition of Lt.-Col. Brittlebank, seconded by Mr. Banham, the audited Balance sheet was received and adopted.

#### ELECTION OF COUNCIL.

The President explained that under the Articles, the members must now proceed to elect ten members of the Association to serve on the Council, in addition to those who held office, and were ex-officio members, and those who were members of Council on the nomination of the subscribing Veterinary Medical Societies.

It was resolved That the following members of the Association be elected members of Council as representing the members of the Fund:—Messrs G. A. Banham, L. J. Blenkinsop, S. H. Gaiger, F. L. Gooch, J. Mc. I. McCall, T. S. Price, H. Sumner, R. C. Trigger, G. H. Wooldridge, W. Jackson Young.

#### EXTRAORDINARY GENERAL MEETING.

Immediately following the General Meeting, an Extraordinary General Meeting was held, at which the same members were in attendance.

The PRESIDENT explained that in order to bring the Articles of Association into line with what was intended with regard to the representation of subscribing societies on the Council, it was necessary to make the following alterations. He moved the following resolution:—

1. That the provisions of the Articles of Association be altered by adding the following words to Clause 18, Sub-clause A (1), after the words "in clause 19 hereof" "so long as these Societies and Associations shall continue to contribute to the funds of the Association a sum of not less than two guineas per annum, and in like manner one representative nominated from amongst the Members of the Association by any other Veterinary Medical Society or Association approved by the Council which may contribute a sum of not less than two guineas per annum to the funds of the Association."

2. That Clause 19 of the Articles be altered by the omission of the words "the Department of Agriculture and Technical Instruction for Ireland" in lines 19 and 20 and the insertion of the words "of the Department of Agriculture, Ireland" after the words "Veterinary Officers' Association" in line 21.

On being put to the meeting the motion was carried unanimously.

The SECRETARY announced that in accordance with the notice duly given, a further Extraordinary General Meeting would be held at the registered offices on Thursday, May 1st, at 6.30 p.m., for the purpose of confirming the Special Resolution.

#### THE CENTRAL VETERINARY SOCIETY.

[NATIONAL V.M.A.—SOUTHERN BRANCH.]

A Meeting was held at 10 Red Lion Square, Holborn, W.C. 1, on Thursday, April 3, at 7 p.m., Professor G. H. Wooldridge, President, in the Chair

The following Fellows signed the attendance book:—Prof. J. Macqueen, Messrs. F. W. Chamberlain, H. King, W. S. King, J. W. McIntosh, J. Willett, G. P. Male, W. R. Davis, W. N. Thompson, P. W. Dayer Smith, G. H. Livesey, R. A. Philp, W. F. Widden, and Hugh A. MacCormack, (Hon. Sec.)

Visitors: Capt. J. B. Leitch, A.A.V.C., Capt. C. J. McNulty, Vet. Corps., U.S.A., Lt. A. Freer, Vet. Corps., U.S.A., Capt. Reavy, R.A.V.C., and Prof. J. J. O'Connor.

On the motion of Mr. J. W. McIntosh, seconded by Mr. Willett, the minutes of the last meeting were taken as read.

The Secretary read a postcard from Mr. J. C. Coleman and a letter from Maj.-Gen. Blenkinsop regretting that they would be absent from the meeting, and also a letter from Mr. Leslie Scott, K.C., M.P., as follows:—

#### HORSES.

Dear Sir,—Lord Ribblesdale and I have been talking over the position with a view to united action by those interested, and we should like to have the views of your Organisation on the question of what action, administrative and / or legislative, should be taken.

Our idea is to get from each organisation concrete suggestions, and then have a meeting at the House of Commons and formulate definite proposals. We should particularly like your views on:—1 Licensing of drivers. 2 Sales of old or worn-out horses. 3 Making the employer penally responsible for offences of drivers, carmen, etc., at least in cases of over-loading or over-working. 4 Forage. 5 Condition of roads. 6 Severe punishment for cruelty. 7 Export trade.

Yours faithfully,  
(signed) LESLIE SCOTT.

The SECRETARY stated that he had written to Mr. Leslie Scott and asked him on what day he proposed holding the meeting with Lord Ribblesdale, and that Mr. Leslie Scott had replied that as soon as the date is fixed he will let me know.

The PRESIDENT suggested that as there was a very full Agenda the consideration of the points raised by Mr. Leslie Scott should be deferred to a subsequent meeting.

Mr. W. S. KING said that he had received a similar letter as the President of the Master Farriers' Association of Central London, and that his Association had decided to wait until a week or two later, as a good many veterinarians belonged to the Master Farriers' Association.

Mr. MCINTOSH entirely agreed with the President's view that the matter should be deferred. The points raised would require very full and careful consideration, and he thought it would be impossible to deal with them on that occasion.

On the motion of Mr. Livesey, seconded by Mr. McIntosh, it was decided to put the matter on the Agenda for the next meeting. The Secretary was directed to inform Mr. Leslie Scott that the matter had been sympathetically received by the Society, and that it would be discussed at our next meeting.

#### RESOLUTION BY THE DERBYSHIRE SOCIETY.

The SECRETARY read the following letter:—

Dear Sir,—I have been instructed by the Derbyshire Veterinary Association to inform you that the following resolution was passed at a meeting of the above Association held on Feb. 21st, 1919:—

#### *Veterinary Surgeons and Live Stock Shows.*

"That Veterinary Surgeons refuse to act in a professional capacity at Live Stock Shows where vendors of animal medicines and surgical appliances are allowed to have stands for the purpose of exhibiting or offering such articles for sale, and also that Veterinary Surgeons attending officially at Live Stock Shows shall receive a Fee."—Yours faithfully,

March 10th. (Signed) F. T. PRINCE.

The PRESIDENT remarked that it was of little use passing a resolution which could not be carried out in practice.

On the motion of Prof. J. Macqueen, seconded by Mr. Davis, it was decided that a letter expressing sympathy with the principles of the Derbyshire Association should

be sent to the Secretary of that Association, but regretting that the Central Veterinary Society were unable to see how they could afford them any useful assistance.

The Secretary read the resolution as follows:—

#### MINISTRY OF PUBLIC HEALTH.

Resolution, passed unanimously at a General Meeting of the Members of the North of Ireland V.M.A., held at Belfast, 28th March.

"That this meeting places on record its appreciation of the action of the Government in introducing the Ministry of Health Bill, and its application to Ireland. Further, having regard to the invaluable assistance heretofore rendered by the members of the veterinary profession to the cause of Public Health, and to the important part which they must in the future undertake in the matter, would point out the necessity of having the words "And a member of the Royal Veterinary College" added to clause (d) of sub-section 2; and at least one member of the veterinary profession on the Irish Public Health Consultative Council; and this meeting requests the Government to provide in said Bill for such representation. That copies of this resolution be forwarded to the Prime Minister, Dr. Addison, the Chief Secretary for Ireland, the Attorney-General for Ireland, and the Ulster Members of Parliament."

The PRESIDENT remarked that without the Bill before them it would be difficult to proceed to the consideration of this subject. In case Fellows were not aware of it, he might tell them that the Veterinary Medical Association of Ireland as well as the North of Ireland Veterinary Medical Association, acting quite independently, had come to the conclusion that it was a serious omission from the Public Health Bill as applied to Ireland that no provision was made in that Bill for the inclusion of veterinary surgeons on the staff to advise in matters appertaining to veterinary work, particularly with regard to meat inspection, and contagious diseases which are transmissible from animals to man. Both the Associations mentioned had sent a deputation over from Ireland to the House of Commons, to interview and to interest important Members of the House in that connection, and although the Bill had reached the Report stage, when it was more difficult to get an alteration made, yet the deputations were still hopeful that they might accomplish their object. Sir Edward Carson had received them sympathetically, and Mr. Devlin had informed them that had the proposal been brought to his notice in the Committee stage of the Bill, it was almost certain that the amendment would have been inserted.

Prof. MACQUEEN thought that the letter should be sent to the National Veterinary Association.

The PRESIDENT said that a similar resolution was before the National Association from the V.M.A.I., which he hoped would be discussed at a meeting on the 10th inst.

Mr. MCINTOSH expressed the view that the Central Veterinary Society should take direct action; he thought there was no time to go to the Council, or to other Societies. There was not a minute to lose; they were probably too late now.

After discussion it was decided, on the motion of Mr. Male, seconded by Mr. Willett, that the meeting should pass a resolution expressing agreement with the North of Ireland Veterinary Medical Association, and submit it to that Association so that they could distribute it to influential members to show that they had the support of the Central Veterinary Society.

Resolved: "That the Central Veterinary Society supports fully the action of the North of Ireland Veterinary Medical Association, and of the Veterinary Medical Association of Ireland in their endeavour to secure the appointment of a veterinary surgeon to the Consultative Council of the Ministry of Public Health."

And further, that copies of this resolution be forwarded to the Secretaries of those Associations in order that they may submit it to the various influential members of Parliament showing that they have the earnest support of their English confrères."

#### VICTORIA VETERINARY BENEVOLENT FUND.

The SECRETARY read the notice from the Victoria Benevolent Fund, convening a general meeting also an extraordinary general meeting to pass resolution respecting the altering of Clause 18 in their articles of association.

The PRESIDENT said that most of the Fellows were no doubt aware that the Victoria Benevolent Fund had recently become an Incorporated Limited Society. That step had been taken on account of the bequest of the late Dr. Clement Stephenson, who had left £5,000 to the Fund, and also a portion of his residuary estate. The notice read by the Hon. Sec. was in effect a notice of the changes in the Articles of Association of the Victoria Benevolent Fund. It would be noticed that any other approved Society which contributes not less than two guineas in any year might nominate a member of the Council of the Fund. The words "approved Society" were included in order to prevent societies other than veterinary societies who might contribute to the Fund, exercising the right which they would otherwise have of being represented on the Council. (It was agreed that no steps on the circular were necessary other than receiving it.)

#### ANGLO-FRANCO BELGIAN VETERINARY RELIEF FUND.

The SECRETARY read the circular letter, dated March 1919 from the British Committee of the Anglo-Franco-Belgian Veterinary Relief Fund.

The PRESIDENT said that it would be remembered that when that Fund was first started an appeal was received, but as it was deemed at that time a little premature, inasmuch as the Fund could not be administered, the amount of subscription from the Central Veterinary Society was not decided upon. It had been agreed, he thought, in general association that there should be a donation, and it was referred to the Council for that purpose. He suggested that the matter should be again referred to the Council. It must be remembered, of course, that it was the Council only that could vote funds, but the Council was anxious to receive suggestions from general meeting, if they chose to give any, with regard to the amount to be voted.

The SECRETARY suggested that it would be advisable to defer the matter until later in the evening, in the hope that the Treasurer, who had been detained by an urgent case, would be able to give information as to the state of the funds of the Society. This was agreed to after a short discussion.

The PRESIDENT: Under the heading of "Morbid Specimens," it has been customary to allow members to refer to any specially interesting cases that have come under notice. He understood that Mr. Livesey desired to mention such a case.

#### FATTY FÆCES IN A DOG.

Mr. LIVESSEY said he would like the opinion and help, if possible, of those members who had experience of a similar case to the following, or of members who were pathologists. The subject was a small griffon about 8 months old, and had been suffering for about three weeks from what he believed was called fatty diarrhoea. The only noticeable symptoms were a persistent greasiness of the skin surrounding the anus, and the passage of pultaceous faeces which contained an abnormal quantity of oil. The dog had been losing flesh, in fact had lost half a pound in weight in ten days, which was a good deal for such a small dog. Otherwise he seemed perfectly well; it was lively, ate well and was in good

spirits. The character of the faeces was really rather remarkable. The food seemed to have been pretty well digested, and it came away in a great dollop of pultaceous matter surrounded with a whole lot of what appears to be oil. This, if gathered up and put on a fire, burned like paraffin oil. If put in a cold place and allowed to cool down, it set, and had the appearance of butter. If the dog lay on a clean white sheet it would leave distinct grease marks from a continual oozing; in fact the dog appeared like an animal which one might suppose had been saturated with liquid paraffin such as was given as a laxative, except that of course that would not set when it got cold. But the faeces were passed in a very similar way, and the dog seemed as if it had had an overdose of oil. He believed such conditions arise in a human being from some interference with the proper functioning of the pancreas or the liver, or both, but that dog did not appear to be suffering from any disease of the liver that he could find; and he knew of no means, in the canine race anyhow, of diagnosing any disease of the pancreas. He had changes of diet, but that did not seem to affect the condition very much. He had stopped milk and butter, and oily foods generally, but that only meant an increased loss of weight. Evidently the oily matter that was passed was not from undigested fats; it was evidently more or less derivative, and apparently was being drawn out of the dog's body and excreted by means of the bowel. He had not come across a case like it; he did not understand how to treat it; and he thought that if a pathologist was present he might be able to help.

Mr. WILLETT said he was in the fortunate position of being able to give Mr. Livesey a little information about the matter, and he thought the President could do so too. He (the speaker) had a similar case about four years ago. The dog had distemper, and up to a certain period was doing well, and then, as in Mr. Livesey's case, he had a motion and dropped the oily matter afterwards, and when the motion set it looked as though candle grease had been dropped on it. He had consulted Professor Wooldridge, and they had decided to stop all oily matter. The dog gradually lost weight, although he was lively and ate well, and eventually became very emaciated. The owner finally decided to destroy him, and a post-mortem was made, when it was found that the pancreas either had been absorbed or was absent altogether. That was the only organic symptom they had found.

Mr. LIVESSEY said that the dog in his case had no previous distemper to account for it.

Mr. WILLETT replied that the condition may not have been a sequel to the distemper; it might have been merely a coincidence.

The PRESIDENT remarked that the two cases mentioned corresponded very closely with regard to the symptoms, except perhaps in the primary history which might have been a coincidence rather than a matter of cause and effect. The fat that came with the stools in our case was always with the latter portion of the stool, and when it got cold it became quite firm and solid, almost like the wax of a candle. It had a distinct butyric odour, and one might have supposed that the dog had too much milk or butter, and those foods were discontinued, but the fattiness continued. He had had it examined analytically by Dr. Lander, who came to the conclusion that it was stearin. They suspected the irregularity of pancreatic function, and in that case they had used some pancreatic secretions, but they got no improvement whatever in the case, and it was ultimately decided by the owner not to persist, and they had the advantage of the post-mortem examination, which, as Mr. Willett had pointed out, revealed a complete absence of pancreas. There was no pancreatic structure at all, and all that was found of the mark of the pan-

crease in the crook of the duodenum was a certain amount of loose connective tissue.

Mr. LIVESY asked what was the age of the dog?

The PRESIDENT replied that it was about six months old, a Pom. It had not occurred to him at the time to examine the urine of the dog, which might help in Mr. Livesey's case. Experimental extirpation of the pancreas resulted in melituria, or saccharine diabetes, and some atrophy of the pancreas may be associated with some sugar in the urine.

Mr. LIVESY asked whether it was believed that the pancreas had been present and had been absorbed?

The PRESIDENT said he thought it had probably been atrophied.

Mr. WILLETT, in reply to Mr. Livesey, stated that he thought the absence of the pancreas was not congenital, because the history of the patient showed that he had been perfectly normal to the time when he had distemper.

The PRESIDENT said that with regard to treatment he could only make one suggestion, namely, that if the condition was associated with atrophy of the pancreas, feeding on fresh pancreas, which could be obtained from the local butcher, might answer the purpose.

Capt. McANULTY, U.S.A., said that he had seen similar cases. He had one Boston terrier bitch of his own, a very good dog, which developed the same complaint every summer. He had it for four years. At times the faeces would be of an ordinary brown colour, and at other times they would be intensely black, but always with these small drops of oily substance upon them. The bitch would lose weight continually while the condition lasted: she would lose from three to seven or eight pounds. He had examined the faeces for the eggs of worms, thinking that might be the cause, because he had seen several cases of lost weight from *Tricocephalus depressiusculus*. That is an ordinary small worm which assimilates the hook worm to a certain extent, but inhabits the caecum, and he had seen many dogs killed by that worm. He found no evidence of the eggs of that particular worm in his dog, or dogs with a similar case and he proceeded to treat them with ordinary intestinal antiseptics. At first he tried salol; which did not seem to improve them much. He then tried thymol, and that did not seem to give much benefit. The dogs would never seem to eat anything but raw meat. If they were given raw beef they would always eat it, but they would not drink milk or eat bread and gravy or greens; they would eat raw grass in quantities, but they would not eat cooked greens. He (the speaker) finally hit upon creosote and bismuth, with the essence of pepper as a vehicle. He had used that quite extensively in the States, and he had given the dogs 3 times daily as much as 20 grains to a dose of bismuth subnitrate, and as much as 2½ to 4 minims of creosote, according to the size of the dog. That treatment after about three weeks produced very noticeable results. He did not get any improvement whatever for about two to three weeks; the dogs would continually lose flesh and be off their appetite altogether. The elasticity of their skin would be absolutely absent, and one would think they were going to die. The day after the treatment the temperature would usually be sub-normal. They do not lose their spirits at all; they play as usual. He had never had the opportunity to hold a post-mortem on one, because they all got well. He might add that most of the dogs had the disease at the seashore. He had seen very few in large cities. He practised in Philadelphia, and on the coast of New Jersey, and he had found most cases at the sea shore.

The PRESIDENT remarked that Captain McAnulty might be interested to know that Mr. Livesey practised at a coast town, the case he (Prof. Wooldridge) had mentioned was in London.

#### ELECTION OF FELLOWS. VISITORS.

The CHAIRMAN announced that the result of the ballot showed that both the candidates for Fellowship, Mr. C. H. P. King, M.R.C.V.S., of 155 Lower Kennington Lane, S.E., and Captain Higgins, R.A.V.C., Woolwich, S.E., had been unanimously elected.

Before calling on Mr. Male to read his paper he would like to extend a word of welcome to several visitors who were present: Captain Leitch of the Australian Army Veterinary Service, who would probably be able to be present at several meetings; two Officers of the United States Veterinary Corps, Capt. McAnulty and Lieut. Freer; Professor O'Connor of the Dublin Veterinary College, and Captain Reavy of the R.A.V.C., who was also Secretary to the Irish Branch of the National Veterinary Association. He was sorry the last two visitors were not in attendance earlier, because they might have assisted us with regard to the Resolution which had been passed with regard to the Public Health Bill for Ireland. Capt. Reavy and Prof. O'Connor were in London at the present time to interview members of the House of Commons, and Prof. O'Connor had told him that he thought it would help them also if a similar copy of the Resolution were sent to them for distribution.

Mr. WILLETT said that perhaps Prof. O'Connor could tell the Meeting when the Report stage was likely to be taken.

Prof. O'CONNOR then made a statement as to the action taken by his Association.

On the motion of Mr. Willett, seconded by Mr. Thompson, it was resolved that the Resolution be also forwarded to the Secretary of the V.M.A.I., with a request that he should forward it as soon as possible to the people whom he knew would be likely to give support in the matter.

Capt. REAVY said that his Society much appreciated the assistance given by their fellow-professionals in England.

#### SOME OBSERVATIONS ON EQUINE INFLUENZA.

By Mr. G. P. MALE, M.R.C.V.S.

(The paper appeared last week, p. 383.)

The PRESIDENT suggested that as the hour was rather late it would be advisable to postpone discussion on Mr. Male's paper until the next meeting.

On the motion of Mr. Thompson, seconded by Mr. Willett, it was resolved that the discussion on Mr. Male's paper should be postponed to the next meeting, and that the paper should be printed and circulated to the Fellows of the Society.

#### THE ANGLO-FRANCO-BELGIAN FUND.

The PRESIDENT suggested that as the Treasurer had not arrived, the Meeting should consider what sum they would suggest should be donated to the Anglo-Franco-Belgian Veterinary Relief Fund.

The SECRETARY reminded the members present that the notice, besides requesting a subscription from the Society as such, urged that individual members should subscribe as liberally as possible; and further, that if they had subscribed, they should subscribe again.

On the motion of Prof. Macqueen, seconded by Mr. Male, it was resolved that a sum not exceeding £50 should be suggested to the Council to be subscribed to the Anglo-Franco-Belgian Veterinary Relief Fund.

#### THE MINISTRY OF PUBLIC HEALTH BILL.

The CHAIRMAN then invited Mr. McIntosh to raise the question of the Ministry of Health Bill for England.

Mr. MCINTOSH expressed the opinion that the profession had been backward in pushing their views as to the inclusion of veterinary surgeons in the Consultative Council proposed to be constituted under the Ministry

of Health Bill. He thought the action of the Irish gentlemen who were present was most creditable. He would be inclined to move a resolution similar to that of the Irish Association.

Prof. O'CONNOR said he was quite sure that Mr. Thatcher, the solicitor to the Royal College of Veterinary Surgeons, was quite alive to the situation. As a matter of fact it was Mr. Thatcher who had written to him calling his attention to the matter.

Mr. WILLETT said it would not be wished to do anything outside the Council, if it could only be known that the Council were doing the best they could for the profession; but nothing was known from year to year until the Annual Meeting came round. Then a small report was issued showing what had been done, and in his opinion that did not tend to give that confidence to the Council which was their due, or which should be their due from the profession who elected them.

Mr. MCINTOSH remarked that the right person to represent their interests was the President of the Royal College of Veterinary Surgeons, and if he had been consulted they would be satisfied that their interests were being safeguarded; but that would not prevent the Society as a Society, or the individual members of it, from approaching Members of Parliament or other people of influence with a view to getting their support and interest. The position at the present moment was so obscure that no one seemed to know whether the Council had been consulted or what had been done, and he thought that if there was any further delay the Society would be too late,—if indeed they were not too late already.

After discussion, it was decided that the President should be requested to see the President of the Royal College of Veterinary Surgeons, or to send him a telegram, to the effect that the Society was strongly of opinion that the veterinary profession should be represented at the Ministry of Public Health about to be formed, in order that the interests of the profession and the Public Health should be safeguarded, and that it would respectfully inquire whether the interests could not be forwarded by personal interviews of individual members of the profession with influential Members of Parliament.

#### THE MASTER FARRIERS' BILL.

The CHAIRMAN then invited Mr. W. S. King to make a short statement with regard to the Farriers Bill at present before Parliament. There would be no time for discussion, but he would like to hear Mr. King's statement on the matter.

Mr. W. S. KING said that as Chairman then of perhaps one of the most important branches of the National Master Farriers' Association, representing some eight or nine thousand members, and as a veterinarian, it appeared to him, that the Master Farriers' Bill was—with the exception of Clauses 2 and 3—of an entirely destructive nature. The only constructive measure which he could see was in connection with the creation of new appointments as examiners for the men who formulated the scheme. In Clause 4 there was a term "or engage in business." That meant everybody; small men who kept a shop, the large railway companies who own horses; the owners of race-horses, veterinarians and others. These people would all have to shut up shop if this Bill became law. He had called a committee meeting of the London district: the Bill was discussed, and he (the speaker) had moved the following resolution: "That this Committee emphatically condemned and protested against the proposed new Bill for compulsory registration of farriers" etc., as calculated permanently to throw out of employment Army farriers and shoeing-smiths who have done valuable work on all the fronts during the war, to render the farriers trade monopoly more severe and restricted than that of the most highly

protected profession, to raise the cost of horse-shoeing far above the present rates, and to inflict serious hardships on all horse owners and agriculturists.

The PRESIDENT said that it might be useful if Mr. King could elaborate a little the effect of the Bill upon veterinarians as such.

Mr. W. S. KING said that Clause 4 of the Bill stated that after the passing of the Act no person should be licensed to practise farriery, unless you served an apprenticeship of 5 years and passed an examination. He thought it was obvious that veterinarians who had shops would have to close those shops if the Bill became law, unless they became licentiates of the Worshipful Company of Farriers. It was absurd to expect veterinary surgeons in the midst of their career to go into a forge and learn the business of farriery so as to enable them to keep forges.

Mr. MALE said that it was of course an insult to ask a veterinary surgeon to pass the R.S.S. examination when he had already passed one ten times more difficult.

Mr. W. S. KING said there was one other thing he would like to mention as affecting the veterinarian. There was an addendum to the Bill, as follows:—"It may be pointed out in the interests of the horse-owning public that it is urgently necessary that some legislation should be passed without delay, as there is a very grave risk of the country being flooded with a large number of semi-skilled men when demobilisation takes place, who, if allowed to practise farriery without restraint, will cause incalculable damage to horse-owners."

That was an insult to the veterinarian who had trained the men in the Royal Army Veterinary Corps. If the men are semi-skilled as has been described, why ask for such a Bill; let the public judge for themselves. Although of course, again, it is a destructive measure, and a most unpatriotic one at that, and, further, it is totally inconsistent with the rights of man.

A vote of thanks to Mr. Male for his excellent paper, proposed by Mr. Willett and seconded by Mr. McIntosh, was carried unanimously.

HUGH A. MACCORMACK, Hon. Sec.

#### DERBYSHIRE VETERINARY ASSOCIATION.

The quarterly meeting of the Derbyshire Veterinary Association was held at Derby on April 8. Mr. A. Levie, of Derby (President), occupied the chair, and there were also present: Messrs. McIntyre, Leek; Harrison, Bakewell; G. Howe, Buxton; J. T. Abell, Derby; J. Deville, Uttoxeter; T. H. L. Duckworth, Ashbourne; F. Aulton, Tutbury, and F. T. Prince, Ashbourne, Hon. Sec.

The President said he hoped they would realise the value of the Association by the amount of criticism of their doings which had already been evoked in the veterinary press. Their object was to make themselves felt as an Association, with the one object of raising their professional status. With that would come fuller recognition from public bodies and from private individuals, and incidentally it would lead to an improvement in their finances. They had been criticised by correspondents who had written to the papers, and also editorially. He for one welcomed such criticism. The editor of *The Record*, referring to their agitation for representation in Parliament, said "It is still doubtful whether a veterinarian in Parliament could exercise more influence upon the Government than can be done by the Parliament of our own profession." But what had the Parliament of the profession done? Absolutely nothing; and there was no indication of their doing anything. "One voice in 700 speaking for one of the

smallest professions in the country would have an uphill task, and the chances of success would depend upon the quality of the man," said *The Record*. He thought that was insulting their intelligence, because if they put a veterinary surgeon into Parliament they would choose a man in whom they had every confidence. Then the editor continued, Any member of the House with a genuine interest in our affairs might do really as much good as one of our profession, though a professional man's knowledge would render a veterinarian preferable if he was suitable in other respects. He (the speaker) believed he was justified in saying that they could not have the personal interest in the profession shown by anyone who was not a member of it, in the same degree as a veterinary surgeon himself would show it. Therefore with one veterinarian in the House they might expect better results than if they relied on the help of their local members. A correspondent in *The Record* who signed himself "Worried," criticised the scale of fees which the Derbyshire Association had fixed, and raised the question of co-operation. Other associations had fixed different fees, and the correspondent in question suggested that want of co-operation between the various associations would be destructive of effort. So far as Derbyshire were concerned they would welcome co-operation, and it certainly existed between their individual members.

With regard to quack medicines at shows, he recalled the fact that they had passed a resolution that they would not attend shows if there were on the ground stands for exhibiting any quack preparations, and one of their critics in the veterinary press was of the opinion that societies would sooner give up veterinary surgeons than the stands of the quack remedy dealers, which were generally very remunerative. "We are quite prepared for them to do that," said the president; "we are not dependent on agricultural shows, and we often attend them at inconvenience and loss to ourselves. That is our reply to that line of argument." So long as the profession was united on that point, he was convinced that agricultural societies would sooner or later come to their way of thinking. He did not want his brother practitioners outside Derbyshire to consider him dogmatic or dictatorial, but he earnestly appealed to them to consider the dignity of the profession and the best means of maintaining it.

It transpired that one or two members had agreed to act for their local shows before the resolution referred to was passed, and it was understood that they might do so this year in the circumstances, but that in future the terms of the resolution shall be rigidly adhered to.

*The Price of Petrol.* The Hon. Sec. reported that he had approached the Anglo-American Oil Company on the question of petrol with a view to veterinary surgeons being supplied on the same terms as other favoured people. He mentioned that some veterinary surgeons already were supplied at the cheaper rate. The company had replied to the effect that it was impossible to supply veterinary surgeons at a cheap rate, and asking for the names of those who were at present being so favoured. It was decided not to furnish the information asked for.

*Insurance Fees.* The President said the next item on the agenda was "Blacklegs of our profession," and in using that phrase what he and the Hon. Sec. had in mind was whether any other practitioner was undertaking work for the insurance companies which members of the Derbyshire Association had refused because the minimum fee was not offered. He invited members present to relate their experiences.

Mr. MARRISON said he had returned several cases to insurance companies, and in three instances the companies had afterwards agreed to pay the minimum fee of 10/6. Another society wrote to say they were con-

sidering the question. He found he was quite as well, if not better off, doing fewer cases at a good fee than a greater number at a poor fee.

Mr. DUCKWORTH produced a letter from the Co-operative Insurance Society who at first refused to pay the 10/6, but subsequently they did so on being told that he would not examine the animal for less, and that no one else in Derbyshire would do so. He agreed with Mr. MARRISON, that although it might mean fewer examinations it would be better for the veterinary surgeon in the long run.

Mr. AULTON said he refused a fee of 4/- from the Imperial, and he afterwards ascertained that the animal in question was insured without being examined.

The PRESIDENT: Let them take the risk if they won't pay the minimum fee. When they have been let in a few times they will fall into line with us. We can afford to refuse a fee of 4/-, which is much too low to offer a professional man who can earn more in other ways. I think we may congratulate ourselves upon the result of our efforts thus far. We expected to lose some business, but much of it will come back, and for what we sacrifice for good we shall be more than compensated in the increased fees. The insurance companies are themselves awakening to the justice of our claim, and they are meeting to discuss a new scale of fees to offer to the veterinary profession.

The Hon. Sec. mentioned that his firm had passed work on to other veterinary surgeons when it lay outside their own district.

The PRESIDENT thought that was a very good spirit to show, and if it only became general it would be a source of strength to them as an association. It manifested a sense of brotherhood and comradeship which their association was out to foster, and he commended the action of Messrs. Duckworth and Prince to veterinary surgeons as a whole.

*Veterinary co operation and Etiquette.* Mr. HOWE spoke on the subject of co-operation among veterinary surgeons and especially among veterinary societies. He thought there was room for a great deal of improvement. He was afraid the powers that be had not looked after the interests of the practitioners as they ought to have done, and especially country practitioners. Unless they bound themselves together and acted as one man their profession would be left behind in this period of reconstruction. Reform was necessary in many directions. To improve their professional status, and above all to secure a uniform and adequate fee from insurance companies and from public bodies generally, they must present a united front. Derbyshire had made a start, and they had come in for a certain amount of criticism, but it seemed a healthy kind of criticism and would, in his opinion, do more good than harm. He hoped that as a result of the lead which this Association was giving, lasting good would be accomplished for the profession. They wanted nothing for themselves that they were not prepared to see others enjoy, but to attain their object unanimity was essential. With regard to the stand they were taking against low insurance fees, it was evident that good was already resulting. They might expect some of the minor companies to refuse to pay 10/6 for an examination, but such companies they could afford to ignore if the larger companies come into line, which there was every likelihood of their doing.

The PRESIDENT, apropos of this question, referred to a report in *The Record* of the ethical code laid down by the Cumberland Association. He said there was a well understood etiquette in the veterinary profession which he believed most men were anxious to observe.

Mr. ABELL thought that membership of a society like this was bound to create a feeling of good fellowship. No man who had the welfare of his profession at heart would care to do that which was contrary to its best

interests. He agreed with the comments made by the President, and said he believed they would further the ideas of co-operation by becoming affiliated with the National Veterinary Association.

The PRESIDENT said there were various ways in which they might co-operate one with another. They could help each other's clients if they happened to be in their district, without, of course, taking the fee that would belong to the client's regular veterinary surgeon. They might also communicate with each other so far as examinations for insurance companies were concerned, so as to make sure that there was no attempt on the part of any company to play one veterinary surgeon off against another. More important still, they could warn each other of clients who never paid their accounts, and so prevent bad debts being incurred. He had not a word to say against the really poor man who could not pay, and he (the speaker) did what no doubt many other practitioners did—attend some sick animals for which he knew he never would be paid. If an animal was in pain, any veterinary surgeon would do his best to relieve it, and in the case of a very poor man the fee would be a secondary consideration. That was not the case he had in mind. They knew only too well that some people who could well afford to pay never did so, and when they had run up an account with one veterinary surgeon they transferred their affections to another. That was where they could do each other a good turn by giving a timely warning. Such people ought to be black-listed, and a friendly understanding among local practitioners should have the desired effect.

*The Council Elections.* The PRESIDENT referred to the approaching election of members of the Council of the Royal College of Veterinary Surgeons. He had hoped that they would have had a nomination of their own, but he was advised that it was too late this year. Voting papers had to be sent abroad and they consequently had to be printed a long time ahead. He proceeded to put in a plea for Mr. Hill, of Llanelli, who was a candidate for a seat on the Council, and who, in his opinion, most nearly approximated to their own progressive views. He did not desire to interfere with the freedom of action of any member in the matter of voting, but he strongly recommended them to give a vote to Mr. Hill.

After some little discussion, in which it was evident that those present shared the President's views, the following resolution was proposed by Mr. Duckworth, seconded by Mr. Abell, and carried unanimously:—

"That the members of the Derbyshire Veterinary Association, having read Mr. Hill's election address in which he proclaims his views on matters of interest to the profession, hereby consider him a fit and proper person to be a member of the Council of the Royal College of Veterinary Surgeons, and pledge themselves to do all in their power to secure his return.

The members had tea together before separating, and decided that the next quarterly meeting should be held at Buxton.

F. T. PRINCE, Hon. Sec.

#### Veterinary work in South Africa.

"In the *Rand Daily Mail* of March 18 we quoted a portion of the latest report of the Secretary for Agriculture, Mr. F. B. Smith, showing that on an Australian or Canadian Basis, South Africa ought to have 400 veterinary surgeons, whereas it only possesses 94, of whom 58 are in the Government service. The livestock in the Union is valued at £100,000,000, an effort is being made to build up an export trade in meat, and later on our breeders may possibly desire to dispose of surplus animals overseas. But our existing flocks and herds are endangered, and the future of the whole industry is

menaced, by the large amount of disease still in the country. Mr. C. E. Gray, the Principal Veterinary Officer, admits in his report for the twelve months ended March 31,\* that different scourges have given a great deal of trouble. Take anthrax, for instance. The Senior Veterinary Officer in the Cape notified 221 outbreaks in the year, and added: "I am confident that the returns do not represent one quarter of the number of outbreaks which occur in this Province." Mr. Gray confesses that the remark applies equally to the Transvaal. In the Transkei and Natal the number of outbreaks showed an increase. In Free State the disease was described as "formidable," whilst Mr. Gray remarked: "What is still more unsatisfactory; in one particular outbreak—in Boshof—the type of disease was so virulent that neither the Institute Pasteur vaccine, nor the local laboratory vaccine had any immediate inhibitory effect on the progress of the disease, and repeated inoculations were necessary before the progress of the disease was stayed." Mr. Gray admits that unless better results are obtained in fighting the scourge, "it is more than likely that other countries will place an embargo upon the introduction of animal products from South Africa, which will react detrimentally upon the prosperity of the farmer, as the country is now reaching a stage in its development when local markets are unable to absorb the output, and openings have to be sought overseas for disposing of our produce." These statements were made nearly a year ago. It is asserted upon high authority that there is to-day more anthrax in the country than ever there has been, and that owing to the evasion of the regulations and the small number of veterinary surgeons available there seems but small prospect of the pest being checked in the immediate future.

Mr. Gray says that the Veterinary Division "has been severely handicapped by the reduction of personnel due to various causes." Clearly, then, South Africa needs more veterinary surgeons, both in the service of the Government and in private practice. Whether it will be able to obtain them is extremely doubtful. A recent letter from a young South African studying veterinary science in England throws some light on the question. Writing on a suggestion that he should make a start in South Africa, he says

"I would not think of accepting the salary they (the Union authorities) offer, and further it is a service in which there are no prospects. Neither would I do private practice in a country where the veterinary profession has no status. I understand that chemists and chartered accountants are protected by law in South Africa, and it is the only country I know of where our profession is still open to quacks. . . . The name of South Africa is mud at the Royal College of Veterinary Surgeons, and I think the only men they are likely to get are the drifters who are taking seven years to qualify."

These complaints disclose the real situation. For years an effort has been made to secure a Veterinary Council and the proper registration of veterinary surgeons. A Draft Act is in existence. The veterinary surgeons desire it. The farmers want it. But year after year the Government allows the damaging and discouraging conditions we have outlined to drag on. Good private practitioners will not come to South Africa to compete with quacks. The best men, not tied down by pension prospects, leave the service of the Government, and others cannot be obtained at the wretched salaries offered. There are men in the Division who have not received an increase in salary for more than fifteen years. They have struggled on year after year hoping for better conditions, but as nothing is ever done they are "fed up" with the whole position.

\* A copy of this report is to hand; we hope to quote from it in an early issue.

Owing to the under-staffing of the Division some of them have had to do routine work in which their highest qualifications are absolutely wasted. Mr. F. B. Smith suggests that a Veterinary College should be established in South Africa, so that we can train our own men. There is much to be said in favour of the proposal, because the diseases in South Africa are often peculiar to the sub-continent. But until the profession receives a proper status, and the Government service is made attractive, we doubt whether a college would obtain many students; and if it did we feel certain that the best of them would soon leave for lands in which the profession is not muddled and ruined."—*Rand Daily Mail*.

#### STATUS OF THE VETERINARY PROFESSION.

Messrs. Willett and McIntosh have taken note of "Dagonet's" expositions on veterinary politics, but "Watchman" on the "status of the veterinary profession" seems to have gone scot-free, whilst his production is ever so much a bigger knock down to the profession than that of "Dagonet."

"Watchman" mentions the word "gentleman." Now one outstanding qualification of a gentleman is courage, and neither "Dagonet" nor "Watchman" seem to have much of it when they have to hide behind a *nom-de-plume*.

"Watchman's" assertion that society holds the veterinary profession in the greatest disdain compels me to ask (1) Has he been successful in his profession? and (2) Has he had the guts to gain the confidence and friendship of the stock owners, large and small, in his neighbourhood, who are an important body. I have an idea he has not; and that he feels a bit "out of it," and not on good terms with his own self.

"Watchman" asks "how many public schoolboys ever dream of becoming veterinary surgeons." I would put it another way, namely:—How many public schoolboys have the courage to enter the profession? or having entered it, have the guts to become successful veterinary surgeons? Very few indeed!

A gentleman recently consulted me about his son, aged 17, who, he asserted, would like to enter our profession. The lad has been brought up in the town, and has no knowledge of horses, cattle, sheep, pigs, etc.—he is fond of dogs and cats. I advised the father strongly to put him to some other calling, as I had seen so many miserable failures where young men entering the profession had no practical knowledge of live stock; and that the only way to know live stock was to grow up with them—in short, that if he did not realise live stock in health he would never know them in disease.

"Watchman's" observations about practising the profession from purely philanthropic motives I look on as "bunkum." Does the doctor, the parson, the barrister practice from philanthropic motives? I trow not. There must be a business side to every profession, and I am truly sorry for the professional man without business instinct, for as the song says, "L.s.d., that is the stuff to bring you joy," etc., and incidentally helps you in society, although money, up to now, has never made a gentleman.

"Watchman" is right when he says "people are judged by the company they keep," whilst at the same time we have to do with so many different specimens of humanity that a tremendous amount of tact is essential.

"Watchman" is against anything of the trades union in our profession. In conclusion, I would remind him that there exists a strong trades union in the medical profession.—Yours etc.,

The Gables, Reigate.

April 28th.

CHAS. A. SQUAIR.

#### VETERINARY POLITICS.

Sir,—I, in my turn have read "with some amusement" the letters of Messrs Willett and McIntosh in your current issue. Mr. McIntosh concludes by opining that unless I am prepared to own to my utterances, I "had better remain in obscurity for ever." Let me assure him, in the first place, that I am not going to own to my utterances, and in the second, that the best way of drawing me from obscurity is for men to write in answer to the aforesaid utterances, as three men have already done to my first letter.

If Mr. J. Willett has read my second letter, he perhaps now understands my attitude upon insurance fees better than when he wrote, so I need not dwell on that point. A more important one, upon which I must contradict Mr. Willett flatly, is his statement that I joined issue with the Central Society *more especially* with regard to District Representation. Now I did oppose District Representation, and I do still; but I *much* "more especially" attacked the strike policy suggested at the Central meeting, which I expressly said was more dangerous than District Representation. I notice that Mr. Willett is quite silent upon this strike policy; and so is Mr. McIntosh, who himself suggested it at the Central meeting.

Both these consciously well-meaning reformers seem much more anxious to criticise their critic than to defend whatever policies they may have advanced. One of these opened a Society's discussion and suggested a veterinary strike, and he would be better employed in defending or withdrawing that suggestion than in asking for my name with an apparent view to a personal attack. The other is a candidate for Council who has not yet issued an election address; and surely one of his "efforts to stir up the lethargy in which the profession has sunk" ought to take the form of informing us what policy he intends to follow upon the Council, if we let him get there. Let him expound his views on this strike question, which really formed the most important part of my letter, and let Mr. McIntosh do the same, and let both likewise tell us fully what they think of the closely related question of whether our profession could be "done without." By so doing they might do much more good than I could by revealing my identity, or than they have done by the letters they have already written.—Yours truly,

April 28th.

"DAGONET"

#### ARMY VETERINARY SERVICE

War Office, April 30.

##### AMENDMENTS TO MENTIONS IN DESPATCHES.

The undermentioned are now correctly described:—

EGYPT.

\* \* \* \* \*  
Gazette dated Jan. 22, 1919 (No. 31138): Kendall, Maj. (T. Lt.-Col.) J., O.B.E. Aust. A.V.C.

Extracts from *London Gazette*

WAR OFFICE, WHITEHALL, April 23.

##### REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Maj. A. E. Clarke, Res. of Off., relinquishes actg. rank of Lt.-Col. on ceasing to hold the appt. of A.D.V.S. (Jan. 12).

Majs. to be actg. Lt.-Cols. while holding the appt. of A.D.V.S.:—H. Greenfield (Jan. 12); A. E. Clarke, Res. of Off. (Feb. 15); (Bt. Lt.-Col.) W. A. Wood (March 5).

Capt. E. Sewell, M.C., Spec. Res., to be actg. Maj. while holding the appt. of D.A.D.V.S. (Jan. 13).

April 24.  
Temp. Capt. G. Sutton, F.R.C.V.S., relinquishes the actg. rank of Maj. (March 25).

April 25.  
The follg. relinquish the actg. rank of Maj.: Capt. H. E. Powell, D.S.O., T.F., on ceasing to hold the appt. of D.A.D.V.S. (Dec. 25); Temp. Capt. W. P. B. Beal (Mar. 20).

Capt. R. E. Beilby, T.F., to be actg. Maj. while holding the appt. of D.A.D.V.S. (Dec. 25).

April 26.  
Temp. Lt. (now temp. Capt.) J. Bell to be actg. Maj. from Aug. 9 to Oct. 7, 1917.

TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

April 28.  
Capt. (actg. Maj.) H. McVean relinquishes actg. rank of Maj. on ceasing to be empld. (March 18).

April 29.  
Temp. Lts. to be temp. Capts.: H. F. Vulliamy (Mar. 7); J. H. McManus (Mar. 8); H. M. Roemmele (Mar. 12).

D.V.S. Temp. Maj. (actg. Lt.-Col.) C. E. Edgett, D.S.O., Can. A.V.C., and to be actg. Col. while so empld. on relinquishing the appt. of D.A.D. of V.S., and ceasing to be graded for purposes of pay under C.P., Cl. 16. (April 14, 1918).

The notifications in the *Gazette* of June 8, 1918, and Nov. 2, 1918, in so far as they refer to temp. Maj. (actg. Lt.-Col.) C. E. Edgett, D.S.O., Can. A.V.C., are cancelled.

### Personal.

KEIR—KELSO. At the Grand Hotel, Glasgow, on the 19th inst., by the Rev. David Keir, M.A. (uncle of the bridegroom), Capt. David Keir, M.C., R.A.V.C., eldest son of Mr. and Mrs. A. Keir, Potterhill, Paisley, to Jessie, second daughter of Mr. and Mrs. Thomas Kelso, Rosemount, Potterhill, Paisley.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1609.

MAY 10, 1919.

VOL. XXXI.

## RECORDS.

It is now practically six months since the cessation of hostilities; but veterinary surgeons in general seem hardly inclined to resume their pre-war professional interests. There is distinct liveliness in veterinary politics, and much activity in agitating for increased fees; but little disposition to scientific discussion or the recording of experience is evident. This is regrettable; for the advancement of professional knowledge is even more important to us than either professional politics or professional remuneration.

The war brought much new experience in both civil and military practice, but not much of it has been recorded. What has appeared has chiefly related to surgery and the more important specific diseases. Some knowledge has been gained regarding the former subject; but it may be said broadly that the war has not brought any great advances with regard to specific diseases in general, though it has made many individual men more expert in dealing with them. Outside these subjects, there is a wide and varied experience which in its sum is of even greater importance to the profession, and concerning which little has yet been written.

In civil practice, two wide fields in which many observant clinicians have learnt a great deal during the war may be mentioned. One is the abundant work upon sporadic affections in animals for which veterinary aid was formerly hardly ever sought unless in the case of an epizootic. Much of this work will probably remain to us, for a considerable time at least; but text-books teach us little of its details, and the men who have learned them in practice know much that could beneficially be communicated.

The second is the great amount of animal disease, much of it very serious, which arose from the bad or insufficient food of war time. In some parts of the Kingdom, including London, many practitioners saw more of the pathological effects of malnutrition than in their whole lives. Whether or not similar conditions ever again arise in England, both practical medicine and dietetics would profit by some records of them.

## A CORRECTION.

In the report of meeting of Derbyshire Society, printed last week, the president, quoting from our issue of Mar. 8th, is reported to have said (p. 401, first col., eighth line) "Any member . . . might do *really* as much good" etc. In the original (second col., sixth line) the reading is "might do *nearly* as much," etc. Phonetically the words are much alike, and it is probably a reporter's error: but there is a distinct difference in the meaning.

## NOTES ON NON-PROFESSIONAL INSPECTORS.

Comments were made at the meeting of the Central Veterinary Society (see V.R. March 29, page 345) concerning the laymen employed by the Board of Agriculture and Fisheries, and with the object of raising a discussion on these inspectors the following notes were penned.

In the first place the method of their appointment calls for criticism. In the interim report of the Departmental Committee that was appointed by the Board to enquire into Swine Fever, the following statements occur, made by Mr. F. A. Fulford, Superintending Inspector of the Animals division of the Board.

"The country is divided into districts, of which there are 17. In charge of every district there is a district inspector, and under these district inspectors we have at the present time (June 1910) 22 assistant inspectors. All of these are what, for convenience, we call lay inspectors, as distinct from the inspectors, who are veterinary inspectors and deal with the professional work of diagnosis."

"Some districts will have two or more assistants in them, and at times, if the work permits of it, the district inspector would work alone. It would depend upon where the pressure of work is greatest. The lay inspectors do the administrative work after the professional officers have told us the disease is there."

"The Board select men who have a general knowledge of the world, who have had experience either in estate offices, or some of them Colonial experience. I myself began as a civil engineer. I was out in the colonies and I have had experience of farming all my life practically. The assistant inspector comes in on trial, I may say, to see how he shapes. Before two years are up he has, if his services are approved by the Board, to go up for a qualifying examination."

"It is a patronage appointment. Reports are made by the officers under whom he has served during his probationary period. The examination is on the Acts and Orders of the Board, and spelling, writing, arithmetic and composition."

The witness was asked, Do you find that that is a satisfactory method of appointment? and the answer given was:—

"I think it has been found to be the very best system possible, because it does not follow that the man with qualifications which would best satisfy the civil service examiners would be best for our work; he might not possess the aptitude for our work, and by this means the Board have an opportunity really of picking the best men for the job. The proportion of failures has been very slight, two or three."

Asked concerning criticism directed against the lay inspectors by agriculturists, the answer was:—

"Yes, I am aware that since the days of our first beginning criticism has been levelled against the

inspectors, on the ground that they did not possess qualifications for the work. The criticism is a very old one now; it started in the days when I first began in 1890, that most of us were ex-officers of either the Army or Navy, and that we did not know one end of a cow from the other. On one occasion that criticism was levelled against myself, who had not the honour of having served in either the Army or Navy. I think it has been very often repeated by people who had never met an inspector of the Board, and certainly did not know the nature of their work, or how they did it."

"A candidate for appointment has to fill in a form, stating his age, giving a brief account of his career, his education at preparatory and other schools, and what he has done since leaving school or college. He has to forward testimonials from people with whom, or under whom he has worked, and give references as to general character. The salary of a lay inspector is £150 per year rising to £250 by £10 a year increment."

"The examination at the expiration, or just before the expiration of the two years' probation came into operation in 1904; but before that, no inspector was promoted to the permanent staff of the Board until he had satisfied the Civil Service Commissioners. One objection to that was that some of these men had been in the service of the Board for a considerable number of years and had thoroughly acquainted themselves with the work, and had done the work to our satisfaction; but still, after the lapse of time they naturally found a difficulty in preparing for and passing the examination—they had got out of the way of examinations—and it was found very hard, after all these years of service, to have to get rid of a man who in every possible way did the work to our satisfaction, but could not satisfy the examiners. Therefore it was thought, it would be better that these men, before they had spent the best years of their life in our service, should know that, provided their work subsequently was satisfactory and their health good, and so forth, they should be able to take up the appointment of permanent officers if it was offered to them."

"The criticism as to the suitability of our officers has been dealt with on certainly two occasions by the Presidents of the Board. Mr. Long in 1896 answered that criticism, and in 1901 Mr. Hanbury did the same, and both repelled the charges in most emphatic language."

Referring to the Veterinary staff, the same witness furnished the following information.

"There is one superintending Veterinary Inspector and 10 veterinary inspectors who are permanent officers of the Board, and 14 assistant veterinary inspectors who are temporary officers."

"In addition to these officers whose whole time is employed in the service of the Board, we have in England and Wales 89 local veterinary officers, and in Scotland six, making a total of 95 who are employed by the Board in dealing with reports of swine fever when one of our own officers is not available."

The writer considered it advisable to give the above extracts, as, so far as is known, no change has been made in the method of appointing lay-inspectors since 1910.

It is seen that these inspectors hold no qualifications that justify their retention to do duty in connection with the contagious diseases. Some of them are tactful, and cloak their ignorance remarkably well, while others presume to pose as experts on all matters concerning the scheduled diseases. They are truly parasitic, and are dependent on the

art of what has been aptly termed "brain sucking," before they can furnish a report.

It has been said by lay officials that veterinary surgeons cannot be administrators, and that administration is the sole property of the layman. This is grossly absurd, as in some of the best administered towns in Great Britain the whole of the duties connected with the Diseases of Animals Acts and Orders made thereunder is carried out by whole time veterinary officials. It must also be remembered that in Australia a V.S. was appointed a few years ago to be administrator of the Northern Territory, and that in South Africa a V.S. was chosen to fill the office of Director of Agriculture. And a V.S. is at present a member of the Board of Railway Commissioners for Canada.

During the recent war the veterinary staff that was retained wisely by the Board has been called upon to carry out a vast amount of work that was formerly delegated to laymen. This work has been done efficiently and economically, and the arrangement has been very favourably commented upon by stock-owners. There is nothing connected with administration that a veterinary inspector cannot do better than a lay official.

During the past there has unfortunately been a considerable amount of overlapping and trespassing going on between veterinary and "administrative" work. In tracing outbreaks of swine fever, for example, it is not uncommon to find that the lay official reports on the health of the in-contact swine. In work connected with diseases of mankind, the sanitary inspector (who has to submit to stringent tests before appointment) is not permitted to encroach on the doctor's preserve.

Much could be written in a very hostile strain against non-professional inspectors, and a catalogue of the stupid things said and done by them could be furnished, but, abuse has its disadvantages, and should be withheld.

Rather let us try and persuade the Board and Stock-owners that these men are superfluous, and that it is not in the best interests of the State that they should be retained. Agricultural societies and Farmers' Unions throughout the country should be put in possession of our grievances; and resolutions concerning the abolition of lay inspectors should be passed and forwarded to M.P. who could discuss the subject in Parliament.

In March, a discussion took place in the House of Commons on the reconstruction of the Board, and it is satisfactory to learn that the Board is now raised to the position of a "first class" department. The writer would be very much obliged for an explanation as to this term as applied to Government departments.

It is hoped that the president will in future be able to lay the demands of the agricultural industry before the Cabinet, and that the Board will receive more financial help from the Treasury.

It is not clear that the officials will be better recompensed.

The Board is to be reconstructed on the lines of the Irish Department of Agriculture, and if this be

properly done, we shall see the end of lay inspectors, because as far as the writer knows—there are no lay officials employed in connection with “dealing with” outbreaks of contagious diseases in Ireland. The subject here raised is one worthy of a full discussion at meetings of Veterinary Associations.

“VIS UNITA FORTIOR.”

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### OVARIAN HÆMORRHAGE.

E. Jost, in an article in the *Archiv für wissenschaftliche Tierheilkunde*, deals with the hæmorrhages and discharges into the peritoneal cavity which occur after ablation of the corpora lutea, rupture of ovarian cysts, etc. The diagnosis of ovarian hæmorrhage is generally not difficult, and is based upon the establishment of the fact that rupture has taken place, and upon the presence of anæmia. In the differential diagnosis the possibility of acute indigestion may arise; but the rapid augmentation of the heart-beats with consecutive diminution of the temperature and marked anæmia should lead the clinician in the right direction. There are various other morbid conditions or consequences of operations upon the ovaries, the chief of which are as follows:—

Young and sensitive animals show loss of appetite, colic, uneasiness, arching of the back, and straining. A similar condition is shown by animals which have strained hard during the operation, cows affected with inflammatory processes of the vagina and rectum, and animals affected with diarrhoea, intestinal catarrh, and John's disease. Cows affected with pyometra not rarely, in consequence of the ablation of a persistent corpus luteum, suffer from tympanitis and colic for some hours. In slight hæmorrhage which ceases spontaneously there is loss of appetite and suspension of rumination, with transient tympanitis. The rupture of ovarian abscesses is followed by grave symptoms of peritonitis, in which case, when anæmia is absent and fever is present, the diagnosis of hæmorrhage may be excluded. In perforation of the rectum produced during the operation, a diagnostic error is only possible in the first hours.

In considering the etiology of ovarian hæmorrhage, the author attaches importance to sanguineous cysts (hæmorrhages into follicles dilated into the form of cysts,) tumours of the ovary (especially angiomas,) tuberculous lesions of the ovary, hæmophilia, and rupture of the ovary. The prognosis is always guarded when the hæmorrhage reaches such a degree that anæmic pallor, a rate of 90 per minute or more in the heart-beats, loss of appetite, suspension of rumination, great diminution in milk production, and general debility are observed. Trembling and clonic spasms render the prognosis absolutely unfavourable. Spontaneous recovery is more easy in young animals; while it is difficult in those advanced in age, especially if the hæmorrhage coincides with the period of heat.

In treatment, absolute quiet and attentive surveillance, with a view to summoning veterinary

help should the condition become worse, are important. As medicaments, caffeine, ergotin, gelatine, and ergot of rye are advised.

The owner should always be warned of the danger of hæmorrhage in consequence of operations upon the ovary; the principal symptoms of an internal hæmorrhage should be explained to him, and careful watching of the animal be advised. Animals which present ovarian tumours or malformations should be excluded from operation. The operator should take care not to rupture the ovary. Cysts should be emptied by puncture with the trocar, which is not dangerous.

It is necessary to avoid extreme straining, so as not to run the risk of the rupture of an oviduct. By systematic compression through the vagina and rectum after the operation, much hæmorrhage may be prevented.—(*La Clinica Veterinaria*).

W.R.C.

#### ANNUAL REPORT FOR THE VETERINARY DIVISION, DEPT. OF AGRIC. UNION OF SOUTH AFRICA FOR THE YEAR ENDING 31ST MARCH, 1918. [Abridged.]

##### EAST COAST FEVER.

This disease continues to be prevalent in some parts of the Union, especially in the Transkei and in Natal. In the Cape, after an interval of over twelve months, the disease again made its appearance in the district of King William's Town. The source of infection is undetermined, but as many illicit movements of cattle from the Transkeian Native Territories undoubtedly take place it seems reasonable to assume that it is to this cause the outbreak may be attributed. The area is now under rigid supervision and compulsory dipping is being enforced.

In the Transvaal, East Coast Fever still retains a footing in five districts. Pietersburg district is in the worst position numerically, there are 21 farms which must be looked upon as actually infected, upon five of which the disease made its appearance during the current year. The greater part of the district is now under compulsory dipping, but a good deal of supervision is necessary to ensure satisfactory results, owing to the large native population.

In the Zoutpansberg there have been nine fresh outbreaks; last year there was only one. One outbreak involving two farms was the most serious, the mortality within the year amounting up to nearly six hundred, owing to the fact that the farm was undoubtedly badly infected before the disease was discovered and no dipping tank was immediately available. More important from an economic point of view, was the outbreak on the Commonage at Louis Trichard, in the course of which 200 head of cattle have died. The abnormal rainfall during the past wet season has been a contributing cause towards the high death rate, as dipping during wet weather cannot be depended upon to give satisfactory results.

In Barberton five fresh outbreaks have occurred and fifteen farms are still in quarantine, although eighteen have been taken out in the course of the year. Some of the existing centres of infection are in parts of the districts which are difficult of access and, although their inaccessibility may tend to prevent the further spread of the disease, it also renders the construction of dipping tanks and the supervision of dipping operations costly and difficult, therefore the mortality on these farms is likely to be considerable before the disease is brought under control.

In Piet Retief, where the position at the beginning of the present year was exceedingly hopeful, we have sustained a disappointing set-back. Five fresh outbreaks have occurred and, although the farms were fenced, they were not tanked and the mortality has been considerable, as the cattle belonged to Native squatters and the European owners have been most dilatory in complying with the Minister's orders to erect tanks.

In the Carolina district great difficulty is being experienced. The outbreaks are confined to the low veld area. Unfortunately the farms in this section belong to non-residents who live in adjacent high veld areas and merely use the infected farms for winter grazing for their sheep. In many cases these absentee owners are indifferent to the welfare of their native tenants and have hitherto ignored and evaded the Minister's orders to erect tanks. Now, however, steps are being taken to have the required tanks erected officially at the owners' expense and the work will be begun at once. The position would be better from an administrative point of view if an owner, in addition to being liable as at present, to have a tank put up at his expense, could be fined for disregarding the order. If this could be done the delays in complying with the Minister's orders, which occur so frequently at present, would be greatly reduced and our opportunities of stamping out the disease would be improved.

Turning to Natal we find that, while the number of outbreaks which have occurred during the year compares very favourably with the record of the year before—84 as against 126—many of these outbreaks have occurred in localities which have been free from disease for a long time, and when they were located the condition of affairs often pointed to the probability that the outbreak had been in existence for some considerable time. Although native stockowners are here so numerous, the larger number of these outbreaks have occurred amongst cattle owned by Europeans. We are occasionally told that East Coast Fever is a less serious menace to the prosperity of the farmer than the regulations enforced to prevent its spread. In a sense this may be true—when a farmer has facilities for dealing promptly with an outbreak, but this attitude is to be deprecated, as it may, and probably does, lead to the concealment of outbreaks and to endeavours on the part of certain owners to eradicate these without reporting to the authorities. Such attempts are fraught with danger to their neighbours, which is materially aggravated when such farms are traversed by a public road. It is always possible for East Coast Fever infection to persist on a farm for a very considerable time without the knowledge of the owner if he is in the habit of dipping his cattle with a fair degree of regularity, because if disease is introduced under such circumstances the attendant mortality may be insignificant and occasional deaths may attract no attention on account of the frequent absence of post mortem conditions which can be regarded as diagnostic of East Coast Fever, the mortality in such cases being often put down to "gall sickness" or to vegetable poisoning. To one or other of these causes I am inclined to think many of these mysterious outbreaks of East Coast Fever which have occurred lately in Natal can be attributed, and I would, therefore, urge upon stockowners the desirability of regarding any deaths of cattle occurring from undetermined causes with suspicion, and of taking blood smears from such cases and sending them in for examination. If this were always done I believe the position would speedily improve.

In some quarters there is a disposition to look upon increased supervision as a panacea, but with this I am not in entire agreement. Careful supervision of the dipping of native owned stock is undoubtedly desirable and necessary. Natives in most instances need help and guidance in mixing the dip, and are sometimes in-

clined to keep their animals away from the tank because of the labour involved in collecting and driving them to the dip. But after ten years of dipping there can be no excuse for the European farmer who neglects to dip his stock properly and regularly.

Meantime many breeders of pure bred stock are subjected to disabilities, which though galling are unavoidable, when they wish to dispose of their animals in other parts of the Union. Stock farmers know that in the dipping tank they have a weapon with which East Coast Fever can not only be fought but can be eradicated, and the sooner those who believe this can induce their neighbours to follow their example and dip their cattle properly and thoroughly the sooner the disease will disappear. I do not mean that the Department should wait for the arrival of this blissful state of affairs, or that it should relax its efforts in the least; but it is only by the combined efforts of the officials and the farmers that East Coast Fever can be stamped out.

I may mention that in the Vryheid Division eight outbreaks out of thirteen are attributed to movements of "salted cattle," which were formerly allowed to traverse infected and clean areas indifferently. For many years the officers of the Department have dwelt upon the desirability of stopping movements of this description and applying the same restrictions to animals said to be salted as to susceptible cattle, and I am glad to say that public opinion has veered round, and this policy is now inaugurated.

*Transkei.* In Butterworth two deaths have occurred in the past nine months: in fact in practically every district where adequate provision has been made for dipping, the natives have taken advantage of it and the condition of the Transkei to-day is infinitely better than anyone who knows what it was like three years ago could have anticipated. Natives are already seeking for opportunities to replenish their depleted herds, so satisfied are they with the progress which has been made in combating the disease. Much of our success is, undoubtedly, due to the harmonious relations which have existed between the Magistrates and the officers of the Veterinary Division, and is a striking illustration of what can be accomplished by tact and perseverance when the Government representative in charge of a district commands the confidence of the native community.

#### TUBERCULOSIS.

The position so far as this disease is concerned is still uncertain and unsatisfactory, and this state of affairs is likely to continue till it is realised that the only way to ensure that co-operation between the stockowners and those administering the Stock Diseases Regulations, which is essential to success and harmonious working, is by lightening the heavy burden now imposed upon the owner by deciding upon a reasonable and generous scale of compensation and making the necessary provision on the Estimates for meeting this expenditure. Pessimists insist that present-day methods are inadequate and that no country has ever succeeded in stamping it out, while others argue that vigorous measures are unnecessary as the salubrious air of South Africa is of itself sufficient to ensure the recovery of infected animals. But there is no doubt that in South Africa when the disease obtains a footing in a herd—even when that herd is kept under fairly favourable sanitary conditions—it tends to spread till a large proportion become infected. For this reason I once more appeal to those responsible for amended legislation and more funds to deal with a disease which, leaving its serious nature so far as bovines are concerned out of the question, is undoubtedly a menace to public health.

*Cape Province.*—Here the Senior Veterinary Officer reports as follows:—"From the prohibited areas (areas

in which the disease is considered to be most prevalent)—the Cape, Malmesbury, Paarl and Stellenbosch—6,139 head of cattle were subjected to the tuberculin test before removal; 111 reacted and were destroyed, a percentage of 1.81 reactors. I am of opinion that Tuberculosis is not rife in this Province amongst ranch cattle, even amongst cattle running on the veld in the prohibited areas. What little there is is confined mainly to the dairy herds which are stabled in and around Cape Town."

I believe that this is a correct estimate of the position, and that it applies to other Provinces as well as to the Cape Province, but the first step which should be taken to combat the spread of Tuberculosis should lie in the direction of making an earnest endeavour to cleanse the sources from which these dairy cows are drawn, thereby making it possible for a dairyman when he replenishes his herd to obtain healthy animals, rather than in attacking the dairy herds themselves in the first instance.

*Transvaal.*—The Senior V.O., Transvaal, holds similar views to those expressed by the Senior V.O., Cape, as to the prevalence of the disease, and urges amended regulations and the provision of increased compensation, in order that the disease may be tackled before it gets out of hand and becomes so prevalent that the suppression or control of the disease is impracticable.

*Natal.*—Here disease was discovered on eight properties during the year; 1,463 head were tested and 27 reacted.

*Orange Free State.*—In the Free State one case was located, the animal being an Ayrshire bull purchased by the British East African Government, which reacted to test when it was applied prior to the despatch of the animal. The animal was one of a herd imported from overseas and was previously tested together with the herd in October, 1914, when no reactions were obtained. Twenty cases of Tuberculosis in animals coming from the Free State were reported from the Pretoria, Johannesburg, Germiston and Durban abattoirs, all in animals the property of speculators obtained from sources which it was impossible to locate.

*Transkei.*—No cases were reported during the year. Government Veterinary Officer Webb has from time to time tested calves from reacting cows in quarantine on a farm in the Mount Currie district, but all have given negative results, which speaks well for the careful manner in which the reacting animals have been isolated.

#### ANTHRAX.

I regret I am unable to report any improvement in the position with regard to this disease. The Senior V.O., Cape Province, where there have been 221 outbreaks in the year, in the course of which 2148 head of stock have been dealt with, says:—"I am confident that the returns do not represent one quarter of the number of outbreaks which occur in this Province."

In the Transvaal, although fewer outbreaks have been dealt with than during the preceding year, there is little doubt that the remarks applied in the case of the Cape apply equally. In Natal the disease is reported to be on the increase; 42 outbreaks occurred; 176 deaths were reported and 12952 head of stock were inoculated. In the Transkei there has been an increase in the number of outbreaks reported, but natives are not backward in inoculating their animals, 41041 head having been under treatment during the year, and in one district—Engcobo—the whole of the Stock Inspector's time has been taken up in inoculating cattle against Anthrax.

In the Free State the number of outbreaks is still formidable, 103 as compared with 134, and in one particular outbreak—in Boshof—the type of disease was so virulent that neither the Institute Pasteur vaccine nor the local Laboratory vaccine had any immediate inhibitory effect on the progress of the disease, and repeated

inoculations were necessary before the progress of the disease was stayed. It may be possible that the unusual climatic conditions had something to do with its prevalence; but the fact remains that the disease, which is a menace to human as well as animal life, is on the increase although a vaccine against it is available the use of which in most instances is attended by satisfactory results. Unless stockowners take this disease more seriously, it is more than likely that other countries will place an embargo upon the introduction of animal products from South Africa.

*Glanders.* There has been a marked falling off in the number of outbreaks of Glanders. Fifteen outbreaks have occurred in the Cape Province, two of these were somewhat extensive, involving the destruction of fifty-one infected animals. The bulk of these occurred in and around the Cape Peninsula. In the Transvaal there were thirteen outbreaks none of them extensive. Natal has always been fairly free from Glanders, and this year there was only one reacting animal destroyed. In the Transkei one case of Glanders only is reported. Four outbreaks were dealt with in the Orange Free State. In dealing with these, 143 equines were tested, ten reacted and were destroyed.

*Lungsickness.* For the second time I am able to report no case of Lungsickness has occurred within the Union.

*Equine Scabies—Mange.* This disease is still fairly prevalent in four districts of the Cape Province. Most of the cases have occurred amongst equines owned by poor whites and coloured people, who do not look after their animals properly. In the Transvaal there has been a considerable increase in the number of outbreaks: most of these were in the Witwatersrand area. Five outbreaks were located in Natal, none of which were extensive: only three were discovered in the Transkei: none were found in the Orange Free State.

*Epizootic Lymphangitis.* In the Cape Province there were only six outbreaks of Epizootic Lymphangitis as compared with sixteen last year. The disease is practically confined to the Humansdorp district, where it has smouldered for many years. During the year a pamphlet was circulated in the district describing the disease and inviting the co-operation of stockowners. In Natal cases continue to occur in the coastal districts. Five outbreaks were dealt with in this area; six infected animals died or were destroyed. The other Provinces are free.

#### CONTAGIOUS ABORTION.

This disease is undoubtedly on the increase. Legislative measures for many reasons are ineffective to prevent its spread, and were it not for the fact that these probably check to some extent the extension of the disease amongst pure bred herds, (we still hope that some satisfactory method may be devised for dealing with it) I should be inclined to advocate the withdrawal of the disease from the Proclaimed Schedule and leave it to the breeders themselves to deal with it. At the present time we assist owners as far as lies in our power, to separate infected animals from those which are free from disease, but animals which have become infected do not immediately respond to the test, and animals which are no longer infective may continue to react, so the carrying out of this work is attended by a good deal of difficulty and uncertainty. In America this disease is regarded as being of the greatest economic importance and, next to Tuberculosis, probably the greatest tax upon the finances of the stock breeder, by reason of the losses amongst calves to which it gives rise; but although similar losses occur here when the disease first makes its appearance in a herd, it is well known that after one or two abortions cows become immune and carry their

calves the full term, even though the cows themselves may still be capable of spreading the disease. In the Cape Province only two outbreaks were recorded, but there is little doubt many more are in existence. The extent to which it is prevalent in the Transvaal is uncertain. In Natal twenty-three outbreaks were reported, and a good deal of work was carried out with a view to enabling owners to separate infected stock from healthy. In the Transkei the Senior Veterinary Officer expresses the opinion that centres of the disease exist in every district in the Territory, but that it is only in Mount Currie that owners report cases for the purpose of having their cattle tested. In the Free State eleven outbreaks were dealt with.

*Swine Fever.* During the year there have been ten outbreaks of Swine Fever in five districts of the Western Province of the Cape, in the course of which 377 animals died or were destroyed.

*Dourine.* This disease has now been definitely diagnosed. As far as we are aware, it is confined to the Herbert district, Cape Province. Leaflets have been circulated containing a description of the disease, and asking owners to report suspected case, but so far the invitation has met with no response. We now know that the disease has existed in South-West Africa for a considerable period.

#### RINDERPEST.

Early in the year alarming reports as to the southward spread of this disease reached the Union from Nyasaland, and according to a pre-arranged plan a small staff, consisting of three Veterinary Officers, with rinderpest serum and supplies left the Union at the beginning of April for the purpose of checking it if that were possible. The expedition travelled from Pretoria by rail to Beira, thence by coasting steamer to Chinde, thence up the Zambesi and Shire Rivers to Port Herald, thence by the Shire Highlands railway and by road to Zomba, and again by road to the south end of Lake Nyassa, then up the Lake by steamer to its northern extremity, then on foot to New Langenberg in German East Africa, which was then within the sphere of military operations. New Langenberg was reached on 11th May. Here the expedition was joined by two Veterinary Officers belonging to the Nyasaland Administration, one from Northern Rhodesia, another from Southern, and two who were lent by the Military authorities, together with four non-commissioned officers belonging to the South African Veterinary Corps.

Steps were taken to locate the disease and inoculation operations were begun; the original programme being the establishment of an immune belt of cattle in German territory along the Northern Rhodesian and Nyasaland borders, and extending from Lake Nyasa to the South end of Lake Tanganyika. There were no European settlers in the area, all the cattle being in the hands of natives, who were until recently under German control. The work was attended by many difficulties, especially in the New Langenberg area, where the numbers of cattle to be dealt with were very considerable. Much of it was carried out in the low-lying unhealthy country bordering on the northern shore of Lake Nyasa under tropical conditions. As time went on the staff of the expedition became reduced by the withdrawal and departure of members of the staff through illness and other causes, till at the end of the year only five Veterinary Officers, two non-commissioned officers of the South African Veterinary Corps, and one European Stock Inspector were available for the prosecution of the work.

From time to time the plan of campaign was modified in the hope of checking the disease without carrying out the entire programme, as the number of cattle which had to be dealt with proved greater than we anticipated,

but when I was recalled at the end of March, 1918, between thirty-seven and thirty-eight thousand head of native cattle had been immunised by the simultaneous method of injecting virulent blood and rinderpest serum, with an average loss of two or three per cent. These cattle are located in the New Langenberg area and in a belt extending from the edge of that district as far as Lake Rukwa. While carrying out this work some members of the staff covered over fourteen hundred miles on foot.

Various problems presented themselves for solution in the course of the work as, in addition to rinderpest, we had reason to believe some outbreaks were complicated with malignant catarrh, while at one inoculation centre which happened to have been established in an area in which East Coast Fever was endemic, and to which a considerable number of cattle susceptible to that disease had been brought for inoculation, we found ourselves confronted with cases presenting a pathological picture of Rinderpest, East Coast Fever, and Redwater all combined, and when the Rinderpest reaction had ceased, the cattle susceptible to East Coast Fever had afterwards to be moved about to shake off the East Coast Fever infection to which they had been inadvertently exposed.

The work of the Expedition at the moment of writing (31st July) is now practically completed, it having been found necessary to carry this out on the lines originally planned, and the members of the Expedition are now on their way back from the south end of Lake Tanganyika to New Langenberg, a distance of nearly 200 miles, the present senior officer being Captain Garden C.V.O., Nyasaland. Needless to say, most of the staff have suffered from the effects of the climate, and whether the ultimate object of the Expedition has, or has not been accomplished and the southward spread of the disease stayed, I can only express my unqualified appreciation of the services of those officers who have borne the heat and burden of the day and seen the work through to its completion.

In spite of the fact, that we have good grounds for hoping the disease may now remain within bounds, one complicating factor over which we have no control has to be reckoned with, and that is the possibility that it may be carried south by wild game, which might bridge the immune belt which has been created—but we must hope for the best.

Two features of the present outbreak struck me forcibly when comparing the type of Rinderpest met in German East Africa on this occasion with that which I met in Southern Rhodesia over twenty years ago. One was the comparative mildness of the disease and the slow manner in which it spread in the areas which it invaded. This is probably due to partial immunity possessed or inherited by native bred animals, and the care with which natives separate sick animals from healthy. The other feature was the small number of reports which reached me as to the ravages of the disease amongst wild game, as only on one occasion did natives report the occurrence of deaths amongst reedbuck and warthog, and that was when we were inoculating cattle near Lake Nyasa, between the Kiwira and Songwe Rivers. In this area, probably through the use of serum weakened through age and kept under unfavourable conditions, or because Rinderpest had already become established in some of the herds before work was begun, the reactions following inoculations were unduly severe, and the mortality unusually high; and here the natives reported that reedbuck and warthog were also dying. Enquiries were made at once, and from these it appeared there had been a certain amount of mortality amongst these animals, but we were unable to obtain evidence at first hand that these deaths were due to Rinderpest. Further North, in another instance, one of the Acting District

Commissioners reported that buffalo were dying in considerable numbers, but up to the time I left German East these were the only reports of mortality amongst wild game that came to our knowledge.

#### MEAT EXPORT.

The business of meat export is developing steadily, and had greater shipping facilities been available, it is certain that a good deal more meat would have gone overseas. The methods of preparing meat for export are capable of improvement, and must be improved—if we are to compete in the world's market, and I would again urge the desirability of sending one or more veterinary officers overseas to study methods of grading, etc., in countries where this business has assumed large proportions, in order that we may benefit by the mistakes of others instead of having to learn by our own. The services of officers with such experience, which could be placed at the disposal of those entering into the business would be greatly appreciated by those interested in the development of this industry.

#### STAFF.

During the past twelve months the Division has been severely handicapped by the reduction of personnel due to various causes. Many officers have been lent to the Military authorities for service in German East Africa, some have gone overseas, the Rinderpest Commission claimed others, and those who have remained have had more than enough to do. It is at times like these that the want of motor transport is severely felt, and although some officers who could afford to do so purchased cars themselves to increase their efficiency, there are others who could not, and their activities have been correspondingly lessened. The present system obtaining, in the case of those who buy their cars either with or without Government assistance, of paying a mileage allowance is, I submit, an unsatisfactory one. As a rule it means that the officer using the car either gains something out of the allowance, or he does not come out on it. My own view is that in cases in which the use of motor transport increases the efficiency of officers by enabling them to cover more ground and do more work—thereby effecting an economy in staff, motor transport should be supplied and maintained by Government, and that more cars should be obtained to supplement the one Government car at present in commission and used by the G.V.O., Johannesburg.

It is with great regret I have to record the loss sustained by the Division by the demise of G.V.O. Dale, an officer of great experience and tact, who died at Durban in July. We have also lost, through death on active service, several of our Stock Inspectors—well-trained officers who could ill be spared.

As in former years, I must once more gratefully acknowledge my indebtedness to the staff generally, both administrative and clerical, to the Assistant P.V.O. for the assistance given me in carrying out the work of the Division, and to the Magistrates, the Police and the officers of the Native Affairs Department, with whom it has been my privilege to co-operate.

C. E. GRAY,

Principal Veterinary Officer.

(The usual returns with tables conclude the report.)

#### ROYAL ARMY VETERINARY CORPS.

The Corps' Annual Dinner will be held this year on Friday the 20th June, at the Savoy Hotel. All officers who have served in the Corps during the war are eligible to attend. It would greatly assist if those who purpose being present will inform me as early as possible.

E. E. MARTIN, Col.,

16 Victoria St, S.W.1. Hon. Sec. to R.A.V.C. Dinner.

#### MILK AND TUBERCULOSIS IN MANCHESTER.

The following is from the report on the Health of the City of Manchester, 1917, by James Niven, M.A., M.B., LL.D.

"In submitting the report of the work done in connection with Tuberculosis and Milk for 1917, I have to say that we have only had the services of a Veterinary Surgeon on one day each week. Mr. J. F. Dixon, M.R.C.V.S., of the City Abattoir, has been loaned by the Markets Committee to the Hospitals Sub-Committee—with serious interruptions, inevitably, no doubt—for the purpose of following up positive station samples of Tuberculous milk and for the examination of the cows within the City. The latter, however, has not been carried out, except fragmentarily.

Mr. J. B. Wolstenholme, F.R.C.V.S., has rendered service on various occasions when Mr. J. F. Dixon was not at liberty. Under these circumstances, it will be readily understood that the work accomplished is less than in the year 1913, when Mr. J. W. Brittlebank, M.R.C.V.S., Veterinary Surgeon to the Sanitary Committee, was able to devote a large part of his time to these duties. At the outbreak of the war he joined H.M. Forces, and now holds the rank of Lieutenant-Colonel. The further distinction has been recently conferred upon him of C.M.G.

Much valuable work has been accomplished, however, during the limited time at their disposal by Mr. J. F. Dixon, M.R.C.V.S., and Mr. J. B. Wolstenholme, F.R.C.V.S.

The number of farms within the City which are occupied as Dairy Farms is 94, whilst the number of cows kept is 1,425.

Sixty-one City Farms were inspected in the year by Mr. J. F. Dixon, M.R.C.V.S., and Inspector Higginbotham. The herds on these farms numbered 968. 35 individual samples of milk were obtained, 4 of which gave positive results. In one instance the whole of the carcass was destroyed as unfit for food. In the case of the other three cows, some portion of the animals was destroyed and the remainder passed as fit for human consumption.

The general condition of the cows within the City has been well maintained, considering the difficulties which have had to be overcome. Many farmers have lost their experienced cowmen owing to the war and to the attractive wages to be obtained in other industries, in which the hours of labour are considerably less. This constant change of farm hands and the substitution of inexperienced for experienced cowmen has led to a reduction in the standard of cleanliness of the cows and cowsheds. Shoddy was found to be in use as bedding on a number of farms. The farmers state that, owing to the scarcity of sawdust, and straw being used as a feeding stuff, they had nothing to fall back upon except shoddy on which to bed their cows.\* Very real difficulties with regard to feeding stuffs have had to be overcome. Many City farmers cannot grow sufficient hay to fodder their cows, whilst the growing of roots on the north side of the City is not practised. In several cases the feeding of cows has been of a hand-to-mouth character, so that much of the cowkeeper's time has been used up in getting feeding stuffs.

#### Dairy Utensils.

The conditions now prevailing are again alleged to be responsible, in a large measure, for several cases of dirty or unsatisfactory dairy utensils that have come to my notice. Owing to the lack of labour, it is more than ever necessary that some simple steam installation should form part of all dairy equipment. A number of the large dairymen and one farmer have high-pressure steam plants. The saving in labour and fuel costs by using steam for all dairy purposes are well illustrated by

\*This is, of course, quite inadmissible.

one farmer, who is also a dairyman, on a large scale. Some two years ago, following an outbreak of Diphtheria caused by infected milk from this farm, a high-pressure steam plant was instituted at the instance of the Medical Officer of Health. The farmer now expresses much satisfaction at the result. All dairy utensils and delivery bottles are sterilised after use, with the result that they have not had any sour milk since the steam installation was put in. The saving on this head alone has been sufficient to cover the outlay. The saving in fuel has been no less marked. Hot water was previously obtained by means of sett boilers heated by coal. Steam is now raised by coke breeze, in sufficient quantities for all dairy purposes and the boiling of pig food, at one-fourth the cost of coal in the old method, whilst the saving in labour is so great that were it not for the steam they would hardly be able to carry on their business at the present time.

#### *The Manchester Milk Clauses.*

The Manchester Milk Clauses have been operated as in former years, so far as the obtaining of milk samples has been concerned and the following up of positive station samples. A change in dealing with the cows found to have positive tuberculous lesions in the udder has been brought about by the operation of the Cattle Sales Order of December 17th, 1917. Our former custom in dealing with an animal from which a positive tuberculous sample of milk had been obtained was for the farmer to send the cows to a Public Abattoir wherever possible, so that the carcass could be inspected and its condition ascertained after slaughter, and the necessary steps taken with regard to the meat if the whole or any part of it was unfit for human consumption. Under the Cattle Sales Order referred to above, all cattle, whatever their condition, if sold for beef, must first be graded at the auction to which they are sent for sale. It may happen, if the farmer is disposed not to inform the Grading Officer as to the known condition of his cow, that it may be graded in a higher class than it would be if its condition were made known at the time of grading and sale. The loss accruing from such disposal of a known tuberculous cow which may not exhibit any patent external signs of Tuberculosis falls on the butcher or association of butchers acting under Food Control Committees. Further, it is almost impossible for a cow to be traced through an auction to its place of destination before the animal has been slaughtered and, in all probability, consumed, so that we are not in a position, either from Manchester or through the Local Authorities, to have the cows inspected by a veterinary surgeon at slaughter.

In a number of recent cases the farmers have informed the Grading Officer of the condition of the animal beforehand, so that the cow has been graded according to its condition. Steps have been taken to have the cow slaughtered locally under the supervision of the authorities. The farmer, under these circumstances, only receives the maximum value of such portions of the carcass as are passed as fit for human consumption.

#### *Tuberculous Milk.*

During the year 330 samples of milk have been collected by the Food and Drugs Inspectors in connection with Tuberculosis. Of this number, 311 were collected at the railway stations, and the remaining 22 from carts coming in by road. In addition, 35 individual samples of milk have been obtained by the Veterinary Surgeon from cows at various farms within the City. The number of farmers represented in the total is 365.

Of these 365 farmers, 35 reside in the City, and 4 (11·4 per cent.); 192 reside in Cheshire, and 26 (13·54 per cent.); 43 live in Derbyshire, and 4 (9·3 per cent.); 23 live in Staffordshire, and 1 (4·3 per cent.); 34 live in Lancashire, and 4 (11·7 per cent.) sent tuberculous milk;

4 live in Yorkshire, Westmoreland, and Cumberland, and none of them sent tuberculous milk.

The following table of samples submitted in connection with the Manchester Milk Clauses summarises the work of the year 1917:—

Specimens of mixed milk taken at the station	311
Specimens of mixed milk elsewhere (for administrative purposes)	22
Found to contain tuberculous infection: Station 30, elsewhere 3. In addition, 29 control samples were taken at the stations and elsewhere, 12 of which were proved capable of causing Tuberculosis.	33
Farms visited in consequence. Of these, 5 belonged to the year 1916.	38
Specimens taken from individual cows as the result of following up station and other samples	125
Milks from individual cows proved to be tuberculous out of those given in the preceding column	26
Udders proved to contain tuberculous lesions	26
Milks taken from individual cows as the result of notification or otherwise than owing to the presence of tubercle bacilli in mixed milk. This relates to City Farms.	35
Udders in last column shown to be tuberculous by bacteriological examination. This relates to City farms.	4
Submitted for examination	522
333 mixed samples—primary. 29 mixed samples—controls. 160 individual cows.	

From particulars supplied by farmers, 258 of whom replied to our queries, we find that on these farms there were 5,221 cows, or an average of 20·23 cows per farm.

Reference to the above tables will show that the percentage of farmers whose milk was examined, and who were found to be sending tuberculous milk, was 10·13 per cent. It will be seen that since 1915 there is a decline. This is all the more satisfactory when the difficulties as to food for cattle are taken into consideration. The country farmer, no less than the city farmer, was greatly hampered in 1917 by the great shortage of feeding stuffs for cattle. They had to rely very largely on their own resources for whatever corn was fed to the cattle. Many farmers have experienced a shortage of hay. Straw had to be fed to cattle in considerable quantities.

Visits were paid to 38 country farms from which tuberculous milk was being sent into the City. The herds on these farms numbered 1820. 10 farms were visited twice owing to the control samples proving tuberculous, whilst one farm was visited four times before the animal concerned was discovered. 26 cows were proved to have tuberculous lesions in their udders; 25 of these were slaughtered, and one remains to be slaughtered.

The farm, which was visited on four occasions before the animal was discovered, had a herd of 12 cows. On the first visit three samples of milk were obtained, all of which gave negative results. It should be noted here that all the cows were first milked down to the stripplings, only the stripplings being drawn for the samples. A control sample of mixed milk proved positive. A second visit was paid in consequence, and three samples of milk were obtained from three other cows. These, likewise, proved negative. These samples were obtained as described above. A second control sample proved positive. The farm was visited a third time, when a mixed sample from every two cows was obtained—one of these gave a positive result. One of the two cows whose milk formed this positive mixed sample was sampled on the first visit, and gave a negative result. In this third instance be it noted the animals were not milked prior to the samples being obtained, but the milk sampled and tested was the first milk drawn from the udders. A mixed sample from two of these cows

was found to be positive. A fourth visit was paid, and two individual samples of milk were obtained from the two cows the mixed sample from which had proved to contain tubercle bacilli. The cow from which a previous sample of milk strippings had been obtained with negative results gave a positive result with the first milk drawn from the udder. It can only be concluded from this that the tuberculous lesion discharged itself in the first milk drawn from the udder, whilst the strippings were free from tuberculous infection.

#### STATUS OF THE VETERINARY PROFESSION.

Sir,—Whilst there is much that is good in Mr. Squair's letter, I feel that a protest should be made against the insinuations made by him in the following sentences :— "How many public schoolboys have the courage to enter the profession? or having entered it, have the guts to become successful veterinary surgeons?—very few, indeed." Mr. Squair forgets the reference by a noted man to "The playing fields" of the schools. The records of Marlborough, Eton, Rugby, Rossall, Tettenhall, Mill Hill, the various Grammar schools, the Scottish schools etc., will prove that whatever other virtues may have been lacking, pluck, courage, and resource have been outstanding features in the public schoolboy. A great many men from these schools have been first rate horsemen, seamen, soldiers, explorers, and the number of men who have led in art, science, commerce, law and literature is quite marked, and in many cases well known. I do not believe, after over quarter of a century's experience, that any special virtues or any remarkable display of pluck is necessary to become a successful veterinary surgeon. Just the old virtues are required—patience, perseverance, assiduity and brains. The rewards are not great but the life has its compensations. Greed and avarice often produce better material results than open mindedness and open handedness, but the latter type of gentleman is the more worthy. There is much in the view that a man is largely what he makes himself—"When the student of veterinary science essays to enter into companionship with men learned in law, medicine and theology he owes it to them and to himself to make himself worthy of that companionship."—Yours faithfully,  
G. MAYALL.

Sir,—There is some unconscious humour and considerable *naïveté* in Mr. Chas. A. Squair's attempt to divert attention from the central theme—the relative veterinary status—by writing a dissertation on "guts." My letter did not reflect on the standing of the individual, and in those circumstances Mr. Squair's personality surmises and deductions are indications that he has not yet mastered the ethics of journalistic controversy. Moreover, in his haste to become personal he has buried himself in the morass of a loose premise, namely, that those who take a somewhat pessimistic view of the relative veterinary status are mere local nonentities who have failed to gain the confidence and friendship of the washed and unwashed of Corngate, Cowdale, Cottonville, Whippetfield, Whitechapel, or wherever they may be located. Mr. Squair will perhaps correct me if I am wrong, but I seem to have an idea that General Sir Frederick Smith, in a paper read before the Society of Arts last December, mentioned that a certain Roman general placed it on record that in Italy the treatment of animal diseases was regarded as a mean and contemptible occupation. Sir Frederick added that although 1500 years had elapsed since the Roman general pronounced judgement, public opinion had undergone very little change in this respect.

Not content with one faulty premise Mr. Squair proceeds to lay down a second thuswise: The public school-

boy has not the courage to enter the veterinary profession, or entering it has not the guts to become a successful veterinary surgeon. The obvious inferences here are that the public schoolboy has less courage and strength of will than the youth of inferior education, and that success in one or other of the numerous branches of the veterinary calling is in inverse ratio to youthful social advantages and scholastic attainments! Carried to a logical conclusion Mr. Squair's doctrine would seem to imply that it needed more courage to become a dustman than a Lord Chief Justice, or a knackerman than a medical officer of health. And this reminds me of the axiom that "To be ignorant of one's ignorance is the malady of the ignorant."—I am, Sir, Your obedient servant,  
"WATCHMAN."

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919 :—

Aulton, F., Tutbury	1	1	0
Chadwick, J. B., D.V.H., Manchester	1	1	0
Edwards, W. W. H., Ludlow, Salop	1	1	0

#### DR. CLEMENT STEPHENSON'S WILL— THE BEQUEST TO ARMSTRONG COLLEGE.

On Tuesday, 6th, in the Chancery Division, Mr. Justice Astbury decided a point arising out of the will of the late Dr. Clement Stephenson, of Newcastle. The plaintiffs were the trustees of the will, the defendants being the Armstrong College and the Victoria Veterinary Benevolent Fund.

Mr. Lavington, for the trustees, said that the point was whether or not the Armstrong College took a share in the residuary estate of the testator. This estate was very considerable. The testator left £5000 to the college, to build laboratories in connection with agriculture. But, in fact, the testator paid the college that sum during his lifetime, thus rendering the legacy not payable. The will gave the residue to be divided proportionally amongst the various institutions "to which I have bequeathed legacies," and thus the question arose as to whether the College shared inasmuch as it had not actually received a legacy but had been paid in the testator's lifetime.

His Lordship held that, upon the clear intention of the testator, the college was entitled to participate in the bequest of the residue.

The trustees are Dr. Page and Mr. J. D. Walker.—*Newcastle Daily Chronicle.*

## ELECTION ADDRESS.

*To the Members of the  
Royal College of Veterinary Surgeons.*

Having been nominated as a candidate for Council at the forthcoming election, I venture to ask the hospitality of your columns to allow me to briefly state my views on one or two of the questions now before the profession.

In the first place I may state that I lay claim to a more than average acquaintance with the practical politics of our profession, as I was for fifteen years Hon. Secretary of the Lancashire V.M.A. and for the past nine years have also been Hon. Secretary of the National Veterinary Benevolent and Mutual Defence Society, and it is scarcely necessary for me to add, have always been extremely jealous of the welfare and good name of our profession.

I feel, however, that the whole question of veterinary politics is rapidly approaching a very critical position, which requires very careful handling at the present moment, as any diplomatic mistakes are likely to lead to far-reaching consequences in the future.

The whole legislation is at present under revision and some of the measures of reform, or shall I say, reconstruction, are bound to affect us intimately.

The Public Health Bill for instance, has passed its second reading in the House of Lords, and will in a few days secure the Royal approval. This measure sets up an entirely new authority, with perhaps, powers so far-reaching as to be compared to those conferred under D.O.R.A. It is not possible at the present to venture a forecast, but that it will very materially affect the veterinary profession may be accepted as a certainty. No Public Health Service can be complete without the fully trained veterinarian, and it is now generally admitted, but unfortunately the public are not yet acquainted with the full extent of our utility. I am therefore in favour of a vigorous policy to secure full recognition of our profession and an adequate protection of our interests, and to this end will support any effort which may be put forth to obtain representation on the Council and Consultative Committees to be formed under the Bill.

The question of fees and salaries paid by public authorities requires early review, as a great majority of the veterinary surgeons concerned are quite inadequately remunerated for the services they render. As a general practitioner I am naturally familiar with the problems they have to face, and shall at all times watch their interest.

The Master Farriers' Bill is, for instance, in my opinion, directly designed to attack the rights and privileges of our calling and requires closely watching.

I am a strenuous supporter of the maintenance of a high standard of education, both preliminary and professional, for the training of our students, and will at no time consent to any relaxation of the high standards aimed at; indeed, if the profession is to make any real advance it must be prepared to accept its responsibilities in this respect.

It is not possible in a necessarily short address to state one's views fully, but if fortunate enough to be elected by my professional brethren, they may be sure that I belong to no clique or faction, and they may rely on my faithful and disinterested service on their behalf.

G. H. LOCKE, M.R.C.V.S.

## ARMY VETERINARY SERVICE

Windsor Castle, May 3rd.

His Majesty held an Investiture at Buckingham Palace at 11 o'clock.

The following were severally introduced into the presence of The King, when His Majesty invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted:—

## THE DISTINGUISHED SERVICE ORDER.

\* \* \* \*

Lt.-Col. MAX HENRY, Australian Army Veterinary Corps

The King then conferred decorations as follows:—

## THE MILITARY CROSS.

\* \* \* \*

Capt. REGINALD VICKERS, Canadian Army Veterinary Corps.

Extracts from *London Gazette*

WAR OFFICE, WHITEHALL, April 30.

## REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Can. A.V.C.—Temp. Capt. E. A. Watson ceases to be secd. for duty with the War Office (Mar. 21).

May 2.

Temp. Qmrs. and Lts., R.A.V.C., to be Capts., under Art. 330, R.Wt. for Pay and Promotion (Apr. 21):—  
T. E. Clarkson, J. R. Devereaux.

May 5

Temp. Capt. C. W. B. Sikes relinquishes the actg. rank of Maj. on ceasing to be empld. as D.A.D.V.S. (Apr. 17).  
The surname of Capt. A. Monro is as now described, and not as in *Gazette* of April 28.

## TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

May 2.

Maj. (temp. Lt.-Col.) A. W. Mason, O.B.E., F.R.C.V.S. (ret. T.F.), is retired, having attained the age limit (May 3), and retains the rank of Lt.-Col., with permission to wear the prescribed uniform.

May 3.

Maj. (actg. Lt.-Col.) E. W. Parks, relinquishes the actg. rank of Lt.-Col. on ceasing to be empld. (April 2);  
Capt. (actg. Maj.) J. Adamson, M.C., relinquishes the actg. rank of Maj. on ceasing to be empld. (Mar. 29);  
Capt. (actg. Maj.) P. Abson, relinquishes the actg. rank of Maj. on ceasing to be empld. (Mar. 28).

May 5.

Capt. (actg. Maj.) J. A. Dixon, (T.F.), relinquishes the actg. rank of Maj. on ceasing to be empld. (April 9);  
Capt. (temp. Maj.) J. L. C. Jones, (T.F.), relinquishes the temp. rank of Maj. on ceasing to be empld. (Apr. 9).

## Ancient breeds in Sheep.

Professor Cossar Ewart, who, it will be remembered is Hon. Member of the National V.M.A., contributes an article on the intercrossing of sheep to the current *Journal* of the Scottish Board of Agriculture, from which the following extract is taken:—

"Of all the sheep now living in the British Islands, the sheep marooned on the small uninhabited and rarely visited island of Soay are the most primitive—they probably closely resemble two breeds of sheep introduced into Britain about 2000 B.C., namely, a breed (the ewcs of which had goat-like horns) probably descended from the Urial (*Ovis Vignei*) still found in Central Asia, and a breed (the ewes of which are hornless) probably descended from the Moufflon still found wild in Sardinia. As the Soay sheep consist of two distinct types which refuse to blend, they are not likely to be as prepotent or as exclusive as the Southdown. In both varieties of Soay sheep the wool is very short and fine, but so close that they are as hardy as the Highland blackface. Further, Soay sheep are long-lived, easily kept and very prolific—a ewe brought from Soay in 1893 died in 1914 after rearing her 32nd lamb. Like the Moorit sheep of Shetland, Soay sheep have never acquired the habit of accumulating fat in the sub-cutaneous tissues—hence they are classed with breeds deficient in mutton characters. In having large horns, long ears and a throat fringe, a narrow-arched back and low, narrow shoulders, long slender limbs and a somewhat low set on tail, Soay rams profoundly differ from plump comfortable-looking Southdown rams, obvious products of intensive artificial selection. At the end of the Bronze age, herds of the Urial-Soay and Moufflon-Soay sheep and of 'four-horned' sheep occurred in most parts of Europe. Remnants of these pre-historic varieties still survived in many parts of the Continent during the first half of the nineteenth century, but by the end of the century the primitive breeds had been supplanted in most areas by improved breeds. At the present day piebald and other varieties of 'four-horned' sheep are still preserved in private parks, but herds of Neolithic and Bronze age sheep of the Urial and Moufflon type are now rarely met with, except in outlying or isolated areas, such as the Faroes and Iceland, Shetland, Soay and the Isle of Man, Brittany, D'ouessant (a small island off the coast of Brittany), the Auvergne, the Alpes Maritimes, the Ardennes, and certain parts of Russia and Western Siberia. The members of the herds in these areas vary in make, coat, and colour, but, with few exceptions, are characterized by a short tail, fine limbs, and an almost complete absence of mutton characters. In the most typical members of the herds, the coat usually consists of fine wool which varies in colour from fawn to reddish-brown—because of the reddish colour of the fleece such coloured sheep are often known as Moorit sheep. The fine reddish short wool forming the fleece of some of the better bred Moorit sheep corresponds to the fine white wool forming the inner coat of wild sheep. We may assume that as the coarse hair inherited from the wild ancestors was gradually eliminated, the fine wool forming this inner coat gradually became pigmented. If we assume further that the least conspicuous individuals had the best chance of eluding eagles, ravens, and other enemies, we can understand why so many primitive 'peat' or 'heath' sheep are of a fawn or brown colour. It may be mentioned that the loss of the coarse hair forming the outer coat was due more to changes in the environment than to selection by the ancient herdsman."

### Sale of Aborting Cows: Testing Cattle for Export.

At the annual general meeting of the National Cattle breeders' Association, held in London, the secretary reported that a copy of the following resolution, passed at the last meeting had been duly sent to the Board of Agriculture and acknowledged by that body.

"That any person who knowingly exposes for sale in a public market, within a period of two months, a cow or heifer that has prematurely calved, will be guilty of a penal offence, and that the Board of Agriculture be asked to insert this in a General Market Order, or alternatively to grant powers to local authorities to insert it in their own market orders."

The secretary was directed to ask the Board what steps they had taken in connection with the said resolution, or whether or not it would be carried into effect.

The question of official testing of cattle for tuberculosis was fully discussed. A resolution from the English Aberdeen-Angus Cattle Association was taken to initiate a discussion.

"That the National Cattle-breeders' Association be requested to consider the possibility of securing an official test for tuberculosis in this country for all animals sold for export, as is already arranged in the case of the United States."

Mr Bridges said that when cattle were tested in this country and passed for export to South Africa, they often arrived there with a high temperature, which might last for weeks. In such a case the animal was

destroyed; this not only affected the exporter, but came back on the vendor as well, because it is not reasonable to expect that the prices here would be as good as they would be otherwise.

The Hon. C. B. Portman said there were many objections to a permanent station for testing, as animals perfectly healthy at home might be infected en route. He was of the opinion that what was wanted was that an official from each country should be appointed to visit the farms and test there. It was finally resolved:

"That a special committee (appointed) be empowered to approach the Board of Agriculture and the breed societies, and to take any steps that may be deemed necessary in order to carry out the resolution mentioned above."

MAY 17, 1919.

VOL. XXXI.

## THE COUNCIL ELECTION.

During the coming week the Annual Report and the voting papers will be issued; and we shall be confronted with the Council election. The present liveliness in veterinary politics imparts some interest to the election, but fortunately no test question is before the electors to give prominence to men of one idea.

It is unquestionable that the profession has reached a critical period in its history, and that the Council, for years to come, will have onerous and difficult duties to perform for us. Present information upon some of the obstacles the Council will have to face is incomplete, and it is certain that the nature of some others is yet unforeseen. Undoubtedly we want good men to grapple with them.

Not a little criticism has lately been passed upon the present Council; but it is a question how much or indeed whether any of it is just. Most of it is merely a symptom of disturbance, and it is evident in almost every section of the nation just now; there is also the natural, though not always reasonable human tendency to abuse those in authority whenever times are hard. On the whole, the Council have done excellent work for us during the recent troublous years; and have secured not a few rights and privileges to members which a careless or inefficient governing body would probably have failed to obtain. A great deal of this is due to the exertions of the President and a few others; and we may agree that the less prominent Councilmen deserve at least some credit for having chosen their leaders wisely and supported them loyally. It is noteworthy that no critic of the Council has anything but praise for its president; and, indeed, there is a singular lack of definiteness about almost all the complaints we have heard of the Council's work. Most of the suggestions that have been advanced for amending it have been equally vague: and some, such as the will o' the wisp of "district representation," are positively mischievous.

We want a Council of hard workers and level-headed men, with the energy, knowledge, and prudence to deal with the many difficult questions they will have to face.

## A VOICE FROM THE PAST.

We reprint this week (p. 418) almost in full, the remarks of an earlier writer on what is now termed "the status of the profession." The writer deals mainly with one phase of the matter, but his feeling is so much in accord with some of the recently expressed ideas, and withal is so thoroughly sound that we have no hesitation in re-presenting them to our readers. Much has happened within—and without—the profession since the article was

written, but it shows us that there were in that day men in the profession whose aspirations for the profession were as keen and as sincere as any of those of to-day. Since then the advances of the profession have placed it more nearly on a level with the medical, even though we admit it an "inferior member." But now, as then, it is the men who show intelligence and self-respect who maintain, and help to raise the status of the whole body.

The extract is taken from the Editorial page of *The Veterinarian* for March 1st, 1830,—fourteen years earlier than the date of our First Charter—it is unsigned, but the title page of the annual volume bears the names, as editors, of Messrs. Percivall and Youatt.

## UMBILICAL TUMOUR AND FUNICULITIS DUE TO SCLEROSTOMES.

Hartog, in the *Tydschrift voor veeartsenykunde*, reports this case. An eighteen months old gelding presented a soft irreducible tumour, the size of a turkey's egg, in the umbilical region. No opening in the umbilical region could be perceived. The nature of the tumour could not be diagnosed till after operation. At the same time the animal showed a hard pear-shaped tumour of the size of the fist in the left inguinal region. This tumour did not extend very high into the inguinal canal, and showed no trace of fistula.

The inguinal tumour was operated upon in the classic manner; but, after dissecting the vaginal sheath, Hartog found that the epiploen had descended into the tumefaction. He therefore twisted the sheath upon itself with its contents, and applied a clamp as high up as possible.

The umbilical tumour was operated upon under local anaesthesia. An incision was made upon the median line, the two lips of the cutaneous wound were separated, and the tumour was dissected to its base. Although he could perceive no opening in the umbilical region, Hartog had the impression that the umbilical orifice was not obliterated in a normal manner, for a loose depressible tissue existed in that place. Supposing that there must be a very narrow orifice in the abdominal wall, Hartog applied an elastic ligature to the base of the tumour, and excised the mass a small distance from the ligature. The tumour consisted of a structureless mass of gelatinous consistence and brownish colour. In its centre, Hartog discovered six armed sclerostomes. It is certain that the neoformation must have been provoked by the irritation due to sclerostomes.

After three days the stump of the testicular cord was excised below the clamp. Incising the mass, Hartog found in it five sclerostomes, several of

which were still living. It is to be presumed that the funiculitis must have been provoked by the presence of the parasites.—(*Annales de Médecine Vétérinaire*).

#### ENTERRHAGIA FROM COMPRESSION OF THE PORTAL VEIN.

Prévost, an army veterinary surgeon, reported the following remarkable case to the Central Society of Paris. A four-year-old mare, in rather poor condition, showed colicky symptoms; and the stable attendant perceived that during the night she had lost by the anus a quantity of blood, which was estimated at several litres. Upon examination, the mare was found to be depressed. The pulse was small and imperceptible, the conjunctiva pale, and the flanks agitated. The vulva was clean, but the margin of the anus was still covered with blood. The faeces were hard and blackish. Manual exploration of the rectum did not reveal the least trauma. The haemorrhage did not recur, but the mare soon died.

The post-mortem examination resulted as follows. When the abdomen was opened, one or two litres of red serosity flowed out. The peritoneum was inflamed, and was largely separated from its attachments in the region of the right kidney, where it formed a capsule filled with pus. There was, therefore, a peri-renal abscess, which was regarded as due to strangles, and which reached the size of a child's head. The kidney was simply congested. The great mesenteric artery was gorged with blood. The portal vein was compressed by the abscess, which had developed insidiously. The resultant venous stasis had produced a haemorrhage at the most dependent part of the large colon, in the region of the diaphragmatic flexure. The vena cava had escaped the compression.

It is rather interesting to note that, in polygastric animals, abscesses of the kidneys have not usually such grave effects upon the portal circulation.—*Annales de Médecine Vétérinaire*.

W. R. C.

#### CHARGES OF VETERINARY SURGEONS.

*Licet omnibus, licet etiam nobis, dignitatem artis veterinariae tueri.—Cicero.*

A recent decision in the Court of King's Bench has afforded matter for gratulation to the general practitioners of human medicine. Mr. Handley, a surgeon-apothecary, had attended a patient during several weeks; and on his bill being demanded, had sent in an account of visits and medicines, and the medicines very few in number. He affixed no separate price or charge to the different items, but placed a sum, and a very moderate one, at the bottom of the list. The patient refused to pay for the visits; but he tendered the amount of the medicines, at the apothecaries' usual price. The practitioner persisted in demanding the whole sum, and, on this, issue was joined.

Lord Tenterden, before whom the cause was tried, was of opinion, that on every ground of reason and justice,—for the respectability of the profession and the safety of the patient,—the medical man was entitled not only to charge for the drugs he might have occasion to use, but to demand a fair remuneration for the

employment of his time and the exercise of his skill: and the jury gave a verdict for the plaintiff to the whole amount.

The importance of this decision is duly appreciated by the general practitioner; not as increasing his emolument, for in the majority of cases that will scarcely be affected, but as relieving him from many a source of annoyance and self-degradation; as giving a new character to his profession, and elevating him to a desirable and deserved rank in society.

The veterinary surgeon, although an inferior member, yet a member of the medical profession, is deeply interested in this decision. He, too, is, of necessity, a general practitioner, for there is and can be no distinction of surgeon and apothecary among us; and there is reason to hope that the dictum of the judge and the verdict of the jury would fully reach him.

What is the usual nature and character of the veterinarian's practice? He is consulted respecting a horse supposed to labour under some disease. He has one, two, or three miles to travel to see him. He finds, on examination, that a physic or diuretic ball, with a little rest, and a few mashies, are all that is required to restore the animal to health and work. But will the price of this ball fairly remunerate him for his trouble? Could he even get bread for his family? What is the most conscientious practitioner to do? He has a right to obtain a just equivalent for his attention and advice, and how must he obtain it? Not by doing anything to injure or torture the poor animal, but by sending more medicine than was wanted, and by doing several little things that might as well be let alone. What is the consequence of this? The owner sometimes begins to suspect that he is making a job of the business; and he becomes discontented, and is loth to employ the surgeon another time, and who thus suffers both in reputation and profit.

His bill—what is it?—why a very fair one in amount; scarcely a compensation,—not a compensation for his labour and anxiety: but its items are composed of moving of plugs, and dressing of blisters, and rubbing in of oils, and administering of clysters, and balls, and drenches, and lotions, and many such like things, savouring of the old farrier's school, and fatal to the respectable character we would assume, and to the assumption of which we are entitled.

There are certain broad lines which mark the various grades of society, and custom has stamped them with authority. This retail way of conducting our profession,—these worse than chandler's shop accounts, must necessarily exclude us from the circle in which we aspire to move; or if, by courtesy, a few of us should be suffered to cross the line, unusual private worth, or literary or scientific attainments, must be our passport, and that of most precarious tenure and value.

The medical profession was the last that was recognised. At this, considering the history of early times, and the character of the early practitioners, we scarcely wonder: nor, perhaps, ought we to wonder or complain that its advance in public estimation has been so slow. The higher branches of the medical profession have now, however, been enabled to vindicate their just and natural claims. If they have not a legal title to an adequate honorarium for the exertion of their skill, common consent, more powerful than any written law, has secured it them; and common consent has likewise sanctioned their demand to mingle with the noblest of the land.

The inferior branches of the clerical and legal professions have long reposed under the protection of the legislature, and of common opinion. To the clergyman a vested property has been assigned, of which neglect of duty can scarcely deprive him. The solicitor may demand his fee for every visit, and for the most trifling advice. Their subsistence is grounded on, or connected

with, the exercise of their intellectual and moral powers; but the general practitioner was the tradesman still: neither law nor custom would grant him aught beyond what he could demand as a retailer of drugs; and both united to trample upon him and degrade him. They made him what he was, and then condemned and punished him for being what they had made him.

To us, poor veterinary surgeons, from our later emergence from absolute barbarism, and the nature of a portion of our practice, and the scandalous imperfection of our education, and the rooted and too-well-founded prejudices of the community, all this more powerfully and more painfully applies; but the decision in the case of *Handley v. Henson*, so important to the general practitioner, gives us likewise the opportunity of liberating ourselves from this thralldom, and that worst thralldom of all, a consciousness of self-degradation. Several respectable practitioners have attempted it again and again. The accounts which they have delivered to their employers have borne considerable resemblance to that of Mr. Handley, or have been drawn up in a more summary, and a better way; but these spirited individuals have been so opposed by the practice of the generality of their brethren, and the prejudice and want of principle of some of those on whose animals they practised, and the absence of legal authority in their favour, that they have been obliged, in a considerable degree, to modify, or rather to nullify their plan, and, in some instances, to abandon it altogether.

An opportunity now offers for the profession, by general consent, and one simultaneous effort, to rid themselves of this source of debasement. Why may not the veterinary surgeon's claim, in future, run thus, "For medical attendance on such a case, from such to such a date?" Then the sum,—shall it be arbitrary, or depend on the whim and caprice of the moment? No—while we do justice to ourselves let us not be unjust to others. At the beginning of our ledgers, or in some place, or under some form accessible to our employers, let us have a scale of charges for visits according to the distance, or time occupied, and for operations, and manipulations, and medicines of all kinds: let an account be entered in our day-book of all that we do; and then let the sum appended to our demand be the actual sum of what we have done, and, as nearly as possible, the sum which we are accustomed to charge in our present despicable way of doing business. We should then have the satisfaction of acting honourably towards others, while we vindicated our own honour; and we should have a ready answer to give, a ready justification to plead, in those cases which too frequently happen to the most scrupulous among us—they who have benefitted by our skill afterwards refusing adequately to remunerate it.

We throw out these hints for the consideration of our brethren. We have been strenuous advocates for reform in veterinary education; and we now point out a way in which veterinary practice may likewise be reformed. By their joint influence we might sooner, and more generally, occupy our proper rank in society: but this we shall never do while we are sent into practice unprepared and untaught; and by this vile system of charging for balls, and drenches, and dressings, are voluntarily and obstinately degrading ourselves.

"Culpā suā damnum sentiens, non intelligitur damnum pati."

Parasitic mange has broken out in the City of Aberdeen, and the Bills and Law Committee of the Town Council have recommended that early notification of all suspicious cases be made, and have instructed Mr. Marshall, the burgh veterinary surgeon, to take the necessary steps to have the disease kept in check or eradicated as soon as possible.

#### NORTH OF IRELAND VETERINARY MEDICAL ASSOCIATION. (NATIONAL V.M.A.—IRISH BRANCH).

##### MINISTRY OF HEALTH BILL, AS APPLIED TO IRELAND.

Owing to the urgency and importance of this matter the president, Mr. J. Ewing Johnston, M.B.E., M.R.C.V.S., considered it necessary to call a special meeting of Council on 3rd March, to consider the advisability of sending a deputation to the House of Commons to interview members previous to the Committee stage of this Bill. It was unanimously decided to do so, and to submit the decision to a general meeting, which was held on the 10th March. At this meeting, which was well attended by members, the action of the Council was enthusiastically endorsed, and Messrs J. Ewing Johnston M.B.E., M.R.C.V.S., and J. A. Jordan, M.R.C.V.S., were requested to proceed to the House of Commons at the earliest possible moment, as they were informed the Standing Committee entrusted with this Bill was to have their first meeting on Wednesday, 12th March.

In view of this urgency the deputation left on the night of the 10th March, and the following day interviewed the members in the House. The Ulster Party were most sympathetic, and those who were members of the Standing Committee especially Mr. McGuffin, M.P. for Shankill Division Belfast, voiced the claims of our profession.

The following, as it appeared in Hansard on the 13th, and 27th March, gives a full report of the proceedings.

Mr. MCGUFFIN: Will the words "engaged in" apply to veterinary inspectors, who inspect cow sheds and the condition of milk cows? The production of milk is a very serious matter in reference to safeguarding against disease.

Dr. ADDISON: This deals purely with training and educational matters. The function of veterinary surgeons in connection with the administration of Acts of Parliament is an important measure which will arise when we are considering what would be the extension of the health service, but is quite a separate matter from the functions of the Central Department. Here we are dealing with the cognisance which the Department is expected to take of the training of persons who will be employed on health service, such as midwives, nurses, etc., so that the other matter does not now arise.

Mr. MCGUFFIN: Is it intended that they will have such powers?

Dr. ADDISON: There are so many big questions of health administration in connection with milk and many other matters, which I think would be properly dealt with when we have specific proposals, which we shall have in the near future, put before Parliament in connection with the development of our various health services, that I do not think I could usefully say anything on the general question raised here. This relates merely to the duties of the Ministry in taking cognisance of training. I am in thorough sympathy with the general purpose of the hon. member, but if once we embark on discussing individual health services and their local administration we shall get outside the intention of this Clause.

Mr. MCGUFFIN: I am not often in the absolute unanimity with the Hon. Member for the Falls Division of Belfast (Mr. Devlin) in which I find myself this morning. I am persuaded that if Ireland had full representation in the House of Commons it might have had a separate Bill. Though legislation by bits is unsatisfactory, at the same time I cannot see why Ireland is not regarded as a special entity in this case, with a Bill specially devoted to itself. The Clause says "Six other persons having practical experience of matters relating

or incidental to." What interests or institutions they are to represent is the difficulty at the moment, and I do not think the Attorney-General so far has been very sympathetic with regard to that. I am sure that the industrial classes should have representation. The time has come when the industrial classes, whose children this Bill is specially set up to protect, will insist on having adequate representation on any body that is going to be appointed. There are many representative organisations of labour in connection with Ireland that might fairly claim to have representation.

There is a matter I raised before in Committee, and on which I was ruled out of order, and that is the question of Veterinary Surgeons. In my opinion they are a very important body, and a professional body whose status cannot be ignored in this matter. We all feel that the very bedrock of this question is the question of milk, and I think no men are more competent to deal with this matter than the veterinary surgeons. I would like, therefore, to have some assurance that, in the selection of this body, men whose judgment and experience are so necessary in guiding us in this matter should not be overlooked, and that adequate recognition should be given to the Irish Veterinary Association. It would be their duty to inspect the cattle for tubercular cases, and to see that the milk itself was free from those germs which are so insidious, and, in many cases, detrimental to the health of the people. I would press upon the Attorney-General the desirability of giving us an assurance that the representation of these men will not be overlooked in so far as it serves the general public interest. I want to say that I am absolutely in accord with the hon. member for the Falls Division of Belfast in this matter with respect to Ireland, but we feel for the moment that we are on the horns of a dilemma. We were not likely to get a Bill for Ireland at the moment. There was not sufficient pressure to produce influence enough on the Government. I say it with all respect to my hon. friend, we had not sufficient influence to do that. I do very much regret that there has not been a special Bill for Ireland. Had we the pluck and the tenacity of the Scottish race, in all probability we would have got it, but, even if the provisions are of a temporary nature, now that they are to be set up, we are all hopeful that the best result will be achieved, and I am very glad my hon. friend is so much in sympathy with the prosecution of this measure to a successful end.

Mr. SAMUELS: I have to thank the members of the Committee for the reception they have given to our proposal. The suggestions which have fallen from different hon. members will, I am perfectly certain, be carried into effect when we are setting up this Council. My lonely friend from the Falls Division (Mr. Devlin).

Mr. DEVLIN: Not a bit lonely.

Mr. SAMUELS: According to certain representations he made it would appear as if he had no influence. He had a dynamic influence by his amendments on the paper, and certainly we did adopt to a very great extent, and were bound to adopt the very valuable suggestions he made. As pointed out by my hon. and gallant friend (Capt. Craig) it would not be satisfactory to state here the names of the six persons. We want to have a certain elasticity in regard to the composition of the Council, and that is why we have largely, if not mainly, adopted the suggestion of my hon. friend, the member for the Falls Division, to have six instead of three as originally intended. If we give a certain amount of elasticity the suggestions made by the hon. members, and the hon. members for Derbyshire, Edmonton and Leeds, will receive the fullest consideration, and I hope we shall have a full working and satisfactory Council. I think it would be most unsatisfactory to suggest names here or to suggest the representatives of interests. In this respect I would adopt the views of the right hon. gentle-

man (Dr. Addison) who set his face like flint against the representation of any particular interests, because if you do that you will have them round like bees and hornets. I can assure the hon. member for the Shankhill Division that his suggestions will be carefully considered, but I cannot give any undertaking in regard to the matters now."

On the 28th March the deputation submitted their report at a general meeting of the Association, and were highly complimented on the success which attended their efforts. It was considered however, that in order to make it certain it was unanimously resolved.

"That this meeting places on record its application of the action of the Government in introducing the Ministry of Health Bill, and its application to Ireland. Further, having regard to the invaluable assistance heretofore rendered by the members of the veterinary profession to the cause of public health, and to the important part which they must in the future undertake in the matter, would point out the necessity of having the words "and a member of the Royal College of Veterinary Surgeons" added to clause (d) of sub-section 2; and at least one member of the veterinary profession on the Irish Public Health Consultative Council; and this meeting requests the Government to provide in said Bill for such representation.

That copies of this resolution be forwarded to the Prime Minister, Dr. Addison, the Chief Secretary for Ireland, the Attorney-General for Ireland, and the Ulster Members of Parliament."

On 18th April a special meeting of Council was called to arrange for a deputation to wait on the Chief Secretary for Ireland (Rt. Hon. Ian Macpherson, M.P.), and the Attorney-General (Rt. Hon. Arthur Samuel, K.C., M.P.), on the occasion of their visit to Belfast. The following members were appointed:—Mr. J. Ewing Johnston, M.B.E., M.R.C.V.S., Mr. J. A. Jordan, M.R.C.V.S., Mr. J. J. Ross, M.R.C.V.S., Mr. F. W. Emery, F.R.C.V.S., and Mr. T. McGuinness, B.A., M.R.C.V.S.

The City Chamberlain kindly arranged with the Chief Secretary for the reception of the deputation on Thursday 1st May at 12-30 p.m. Accordingly the deputation as above constituted, were introduced by the Lord Mayor.

The Chief Secretary after listening most attentively to our case expressed himself as being in sympathy with our claims, and gave us such assurance that our profession would be recognised in the Bill which he was contemplating introducing at an early date, as to leave no doubt on the minds of all those present that, at least, our profession would yet be placed in that position for which we have been aspiring, and to which we consider we are justly entitled. (See p. 428).

#### NORTH MIDLAND VETERINARY ASSOCIATION

[NATIONAL V.M.A.—NORTHERN BRANCH.]

A meeting was held at the Grand Hotel, Leopold Street, Sheffield, on March 4th. The following members were present Messrs W. Collinson, (President) S. E. Sampson, R. Hudson, S. H. Nixon, W. Murgatroyd, T. C. Fletcher, H. Thompson, and J. S. Lloyd. (Hon. Sec.) Mr. J. Malcolm Armfield, Visitor.

Prior to the meeting the members present were entertained to tea by the Sheffield members.

The minutes of the last quarterly meeting having been published were taken as read, and on the motion of Mr. Hudson and seconded by Mr. Sampson, were confirmed.

The Hon Secretary read the minutes of the Council meeting held on February 18th, and on the motion of Mr. Hudson and seconded by Mr. Murgatroyd, were adopted.

Mr. SAMPSON, President of the Yorkshire Veterinary Society, stated that he had brought to the notice of that Society a circular letter on veterinary examination fees for insurance companies, issued by the North Midland Veterinary Association, which met with the approval of the Yorkshire Society members with one exception—they thought 1/3d. per mile after a distance of two miles should be charged, instead of 6d. per mile after three miles as stated in the circular. The members present did not agree to this, especially as it was understood that the insurance companies objected to paying any mileage at all.

The Hon. Treasurer submitted a balance sheet for the year 1918. On the proposal of Mr. Fletcher, seconded by Mr. Hudson, this was passed. The Hon. Treasurer commented on the fact that the balance in the bank had been increased from £31 0 0 to £37 10 0 although the subscriptions were considerably cut down, owing to the absence of several members serving with the Army abroad whose subscriptions during the period of war had not been collected.

The PRESIDENT stated that owing to calls upon his time he had not been able to present an address in writing. He wished to thank the members for the honour of re-electing him president, and was particularly pleased to be president in the year when, he had no doubt, peace would be declared. He hoped during his year of office to welcome Army Veterinary Surgeons returning from the war, and trusted they would turn up at the meetings, and be able to give some interesting information to members who had not been fortunate enough to serve. He saw no reason why veterinary surgeons should be downhearted for he thought the greatly increased value of farm stock would call for increased services by veterinary surgeons. Professional fees had been considered by this Association, and increases agreed upon. He thought suggestions from other Associations should be put into the veterinary press, and that steps should be taken to make non-members of Veterinary Associations fall in line.

He drew attention to the great increase in parasitic mange in this country, and thought it probably due to infection from Army horses, mostly, in his opinion, from home units. Horses returned from overseas would also probably bring other diseases, and that would of course increase the work of veterinary surgeons.

He informed the meeting that a conference of West Riding veterinary surgeons was being held shortly at the County Hall, Wakefield, for the purpose of giving information as to treatment, isolation and disinfection in connection with outbreaks of parasitic mange. He was pleased this meeting was being called as it showed that veterinary surgeons were being looked to for advice, and he trusted that a successful issue would result from the conference.

He again thanked the members for his re-election and requested the members to freely discuss any matters mentioned in his address.

Mr. T.C. FLETCHER said he was pleased Mr. Collinson was President in Armistice and Peace years. He wished peace had come in his own year of occupation of the presidential chair.

It was not his opinion that army horses had spread parasitic mange in Sheffield. He was pleased the question of fees had been taken up by the Veterinary Associations in Yorkshire and Derbyshire, and hoped other associations would do likewise. He hoped papers would be brought before the association on current subjects, such as joint-ill in the foaling season. It was very little use discussing specific diseases unless they were prevalent at the time of discussion, when matters relating thereto were fresh in the memories of the members discussing the subject. Methods of treatment as well as experience should be given on this and other seasonal ailments.

Mr. HUDSON said he had a surprisingly small number of parasitic mange cases due to army origin. He thanked Mr. Collinson for taking the chair for another year, and hoped he would have a successful year of office.

Mr. COLLINSON said he had seen outbreaks of parasitic mange on farms when nag horses had recently been brought on to the farm, and thought that it was unusual for mange to break out amongst working farm horses except when it was carried to the farm in the manner indicated. He thought the farmer's nag horse was stabled at Market Inns in stables where horses recently purchased from the Army, and horses of small dealers and wagonette proprietors had been recently stabled. The nag horse in this way caught the disease and carried it to the farm. He thought the use of wood stables greatly increased the probability of infection, for it is almost impossible to thoroughly disinfect such buildings. He also considered that in outbreaks of parasitic mange it is essential that all harness, utensils, etc., should be thoroughly disinfected, or further outbreaks of the disease would take place.

Mr. SAMPSON wished to thank Mr. Collinson for his address and for taking the presidential chair. He thought the increase of parasitic mange was to a considerable extent due to bad grooming, which was aggravated by a shortage of labour and inefficiency on the part of carters. He also thought that the blacksmith's shop and the shoeing smith were probable means of conveying parasitic mange from one horse to another. He thought blacksmiths' aprons and rugs at shoeing forges, and the forges themselves, should be periodically thoroughly disinfected.

He suggested that during the coming summer joint meetings of the Yorkshire, Derbyshire and North Midland Veterinary Societies should be held. He thought that discussion on such matters as veterinary fees at joint meetings would be beneficial and that unanimity would be gained better than by holding separate meetings.

Mr. MURGATROYD stated that he had met with parasitic mange in several army horses a year or two ago. He stated that he had seen it mentioned in a lay-paper that a prominent member of the veterinary profession had stated that a horse can be dressed for parasitic mange at a cost of 2d per dressing, and he had been requested by at least one of his clients to make the same charge. He thought it was a pity that such a statement should have been made and allowed to go out to the lay-press.

In connection with the treatment of parasitic mange Mr. Hudson thought that steps should be taken to prevent quacks from carrying out the treatment, but that it should be confined to veterinary surgeons.

The Hon. SEC. stated that treatment in his opinion was often ineffectual in obtaining a complete cure for parasitic mange because the necessary steps were not taken for removing the hair and thoroughly cleansing the skin of the animal before the dressing was applied. He was also of opinion that method was required in dressing the animal just as it was required in disinfecting the stable. His instructions in connection with the latter were always to have the under-parts of the manger and other inaccessible places thoroughly washed and disinfected before the other parts were attended to. In the same way he thought that the under portion of the horse's body should be dressed before the dressing was applied to the back, loins, and upper parts of the body. Where the latter were attended to first, it was his experience that the under portions got neglected. He also mentioned that isolation was not so strictly enforced under the Parasitic Mange Amendment Order, and stated that his experience in this respect was that if a man was able to work his horse he was not so likely to

dress it regularly as he would if he was forced to effect a cure before the horse could be taken out and worked.

Many members mentioned the difficulty in obtaining specimens of the Itch mite from animals affected, and in this connection Mr. Hudson stated that he took the scrapings, put them in warm water and washing soda, keeping the solution warm for several hours. He then put the sediment between slides and examined with the microscope, usually with success.

Mr. THOMPSON stated that on several occasions he had found the mites by the following simple method. He took the scrapings, put them in an ordinary glass bottle, which he afterwards corked and kept warm for some time. This in many instances could be done by simply placing the bottle in the waistcoat pocket and carrying it about with him. The mites could then often be seen moving up the glass.

#### MASTITIS IN THE COW.

Mr. HUDSON opened a discussion. He said :—

When asked at the last meeting to open a discussion on Mastitis of the Cow, introducing some of the prominent features from the book on that disease by Sven Wall, I did not think my task would be very difficult. Expecting to find original matter, I thought it would be easy to pick it out and place it before you for discussion, but, so far as Mastitis—leaving out Tuberculosis and Actinomycosis, is concerned, I regret to say that I found very little that would further our knowledge of the disease or help in its prevention and treatment.

After dealing briefly with the anatomy and physiology of the udder, the author describes the udder disease which we call Mammitis or Mastitis, under the heading Infectious Mastitis, thus regarding all cases as due to the introduction of some organism.

Infectious Mastitis he divides into Parenchymatous Mastitis—that in which the teat duct, sinus, gland ducts, and epithelium are involved. Interstitial Mastitis—when the connective tissue lying between the secretory ducts, cells and alveoli are involved.

Interstitial he further sub-divides into Acute and Chronic.

He then goes on to describe at some length Mastitis as produced by particular micro-organisms,—Streptococcus Mastitis, Staphylococcus Mastitis, Coli-bacillus Mastitis, Pyo bacillus Mastitis.

It is better, I think, to disregard the division of Parenchymatous and Interstitial, and base our study of the disease on the particular organism which may have brought it about. I cannot picture in my mind ever seeing a case where I could determine either condition existing alone, and certainly not where any of the organisms the author mentions were present: and on reading through the text I have difficulty in seeing clearly that the author has found them as well defined, separate conditions.

The presence in the milk of the udder of any of the organisms mentioned, would, under suitable conditions, soon set up an inflammation, rapidly spreading through the epithelium to the surrounding connective tissue.

*Sources of Infection.* The author appears to take the view that the milk in an apparently healthy udder is always germ free; though later on (page 66) he contradicts himself by mentioning that he found streptococci in what appeared to be normal milk.

The translator introduces a statement by Ward that the healthy udder harbours bacteria throughout the whole of its extent. I think that we are bound to accept that statement because it is generally held to be true by many bacteriologists.

The ports by which organisms gain entrance, the author considers, are openings into the udder,—teat orifice and wounds, and the blood.

The factors predisposing to a teat infection are dropping of milk from the udder when overdistended, and the author considers that a rapidly growing or mobile organism could so infect the whole of the milk in the udder. Age and chills, he thinks, paralyse the sphincter muscle and so allow the organism to penetrate. Introduction by tubes and straws by attendant, and straws penetrating when lying down he also mentions.

The author considers that an organism might grow its way along the teat duct if it is virulent enough to exert a negative chemiotactic action on the leucocytes in the duct, and thinks this explains the distinctly contagious character of many cases of Mastitis.

*Udder Wounds.* Mastitis resulting from these require no comment and can be passed over.

*The blood as a port of Infection.* The author considers that organisms may be arrested in the udder when circulating in the blood stream, either free or carried by leucocytes, the latter dying and leaving the organism to carry on and multiply.

I have often thought that this mode of infection might take place in those cases which are so common where septic conditions of the womb exist, for in such cases it is difficult to imagine the blood being germ-free, also it is evident the blood does carry germs from the womb—as shown by joint and tendon infection, lung infection, sub-dermal infection. Whatever the particular organism may be, it does not appear possible to determine clinically what symptoms it sets up in the udder, so that the microscope would have to decide. The author mentions experiments in which he injected organisms, but the results are no use for diagnostic purposes.

#### TREATMENT.

Under Strepto-mycosis the author mentions for the treatment of general conditions :—Camphor in V grain doses, because it is excreted in the milk (V grain probably means V grammes). Antifebrin because it does not taste in milk. Glaubers salts.

For local conditions—milking out and injecting 300-500 c.c. of lukewarm, boiled 4% boric acid solution, the solution remaining for about four hours.

Rubbing in a concentrated solution of Iodine as a mild irritant for a day or two.

Drawing the udder twice daily, but not oftener, so that the udder may rest.

If the condition is obstinate, the inflation with air inhibits the growth of bacteria. One may combine boric acid solution and air.

Cutting off the teat. Deep firing. Operative removal of sequestra.

Mr. SAMPSON considered that the pathology of these cases was not properly understood, as many of them had not responded satisfactorily to the treatment generally adopted. He would like to be able to treat infectious cases of Mastitis by the use of vaccines or Polyvalent serum.

Mr. COLLINSON had tried a vaccine prepared by taking one part of the disease discharge and three of normal saline solution. This was treated by warmth, filtered and sterilized for ten minutes. He afterwards injected 10 c.c. hypodermically once daily for three or four injections. He thought the injection of filtered air, especially disinfected by the use of eucalyptus, would be beneficial. He did not put much faith in amputation of the teat, for the opening to the udder soon became choked up by the drying of the discharge.

Mr. FLETCHER thanked Mr. Hudson for introducing the subject. This disease was very rife in his practice last season, in August and September. He considered "August bags" arose from changes in the milk in the

udder due to hot weather. The disease was usually found in "lying off" cows. He would very much like to see some successful measures brought forward, both for cure and prevention. He wondered whether a seal on the end of the teat would be of value, or if the change *was* really due to the heat in the milk in the udder. Infection by the blood stream was an interesting method of infection, but he did not remember a case of such occurring from disease of the womb. He thought the mammary lymphatic glands would act as a filter. He thought some means of prevention would really be of more service to the owners of cattle than methods of cure.

Mr. HUDSON thought that if a mixed vaccine was prepared from a special case and injected into the teats of "lying off" cows subject to infection, prevention would probably be successful.

For treatment I have used an autogenous vaccine prepared as follows:—Take a quantity of material from the udder of an infected cow, and add four times the quantity of normal saline solution. Shake well and incubate for twelve hours at a temperature of 100 to 110 deg. Fah. Sterilize by boiling on the water bath for ten minutes, and filter through cotton wool put at the bottom of a 2 oz. syringe, making up any loss by an addition of normal saline solution. Add 5 minims of carbolic acid to keep the vaccine.

*Dose.* 10 c.c. daily injected into the skin at the front of the udder.

It is probable that better results would be given if the dose was gradually increased, but how much increase I cannot say, not having had sufficient experience.

I think that if some treatment were carried out on these lines by members of the Society, and the results compared, we should have better data to base our line of treatment on. If members care to send me materials from diseased udders I will prepare the vaccine and return it to them for use.

Mr. THOMPSON thought that such a vaccine could be prepared at the Pathological laboratory at the Sheffield University, and suggested that steps should be taken by the Association to get into touch with the professor in charge of the laboratory to see if he could assist the members of the Association in this matter.

The meeting concluded by a vote of thanks to the President for his conduct in the chair.

J. S. LLOYD, Hon. Sec.

ROYAL COUNTIES  
VETERINARY MEDICAL ASSOCIATION.  
[NATIONAL V.M.A.—SOUTHERN BRANCH.]

At a General Meeting held at the Laboratories of the Board of Agriculture and Fisheries at New Haw, Weybridge, on Friday May 2nd, the President, G. P. Male, Esq., in the chair, there were also present, Messrs. A. E. Willett, J. W. Willett, Sydney H. Slocock, Esmond Brown, P. J. Simpson, (Major R.A.V.C.), G. Rees-Mogg, (Major R.A.V.C.), J. Willett (Treasurer), H. A. MacCormack, J. W. McIntosh, J. H. Parker, Sir S. Stockman, Messrs. J. C. Coleman (Secretary), and G. E. King.

Visitors: Messrs. M. J. Reidy, D. Starkey, G. A. Koch, H. Gooch, E. L. Lloyd, W. G. Wragg, F. S. H. Fores, O. Knight and A. Norman.

Minutes of last meeting were taken as read and confirmed.

The Secretary read a letter from the Derbyshire Veterinary Association; also one from Live Stock Offices Association, re V. S. fees; and an acknowledgement from Secretary R.C.V.S. of the resolution sent by this Association at its last meeting.

The CHAIRMAN: At our last meeting Mr Willett was appointed a representative to discuss the fees paid by insurance companies. Perhaps we had better take this letter first. Are there any observations on the letter from the Derbyshire Association?

Mr. WILLETT: I quite agree with the last part if it is possible to have the fee, but I think the other part is rather impracticable. Judges usually do not receive a fee, but they usually have their expenses paid.

The CHAIRMAN: I think it should be left to the veterinary surgeon himself to decide. Then there is the question of the veterinary surgeon who refuses to officiate. It would be very difficult to abolish. Perhaps the best way will be to acknowledge the letter with thanks.

Mr. WILLETT: And that this Association does not see its way to express its opinion in the matter. Personally, I think it is rather showing the white feather. It will not stop the patent medicine vendor being there. It is perfectly certain they will not lose their revenue. I think we as sportsmen should come forward to help shows, and help agriculture and the horse breeding industry generally, and I think it would look rather bad if the profession struck against doing its work unless they were paid, and, as Mr. Male says, judges come forward, and I do not see why veterinary surgeons should not. Perhaps the best way will be to acknowledge the letter and take no action. This was seconded and carried.

The CHAIRMAN: At the last meeting, if you remember, we discussed a letter from Mr. Adams on the re-adjustment of fees for the examination of horses for insurance. I wrote to the Committee concerned and we appointed Mr. Willett to represent us. (The Secretary read the reply.)

The CHAIRMAN: We have had a letter sent up with regard to the Milk Bill. Evidently the Council are taking the matter in hand, and although the Committee which was appointed to deal with the Milk Bill did not meet, another committee was formed.

The SECRETARY: I received a letter from the Sanitary Institute asking us to appoint a delegate to the Congress which will meet from July 28th to August 4th. It was too late to put on the Agenda.

The CHAIRMAN: Is it your wish that we appoint a delegate to the Congress of the Royal Sanitary Institute. Now that they have started again is it your wish to appoint one or two.

The SECRETARY: It is rather important just now that we should have delegates.

Mr. WILLETT: Our debates have always been relegated to the last day and any recommendations to the Congress have thus been of little use. I think we should make ourselves felt, and if we do make recommendations they should certainly receive consideration, and not be dealt with as I was when I represented the Central at Cardiff. Other delegates have had the same experience as I had—that our recommendations have been too late.

The CHAIRMAN: I see there is a conference of veterinary surgeons. Newcastle-on-Tyne is rather a long way, and expensive. I think we should ask the Sanitary Institute for some assurance that it is not to be relegated to the last day. They don't do much for us. I think we should hold our own in the matter and enter a protest against being served as we have been served in the past.

Mr. WILLETT: I think we might with advantage ask what arrangements will be made if we go; and we might provisionally appoint a delegate. I propose we provisionally appoint the President to represent us.

The CHAIRMAN: I was the delegate to the last Congress at Blackpool, and I think it is only right that someone else should go this time. I should like to propose Major Simpson, he is a man of some leisure and great ability.

Major SIMPSON: I think you ought to have someone more in touch with veterinary matters.

Mr. WILLETT: It has been proposed that the Chairman represent us. (Carried.)

Mr. WILLETT: As to the fees allowed. I take it the Society pays the expenses—probably two days will be sufficient. At any rate none of the previous delegates have put in very much for their expenses. It is therefore an instruction to the Secretary to write to the Sanitary Institute and ask for information.

The CHAIRMAN: The Secretary will write and ask for information, and express the wish that it is not held on the last day, and any expressions of opinion received will have due consideration. We shall hold a meeting just before, on July 25th, and there will then be time to consider any reply. We shall have to pay the guinea fee, however, which includes a ticket for the conference.

Mr. WILLETT: Leave it to the President and Secretary to decide if the reply is satisfactory. I will send the guinea when I am satisfied that it is in order.

*Nominations.* Mr. WILLETT: I beg to propose my brother.

The CHAIRMAN: Proposed and seconded that Mr. A. Willett be a member of this Association. (Carried.)

*Place of next Meeting.* CHAIRMAN: During the war we have held meetings in Reading. Now we could have a deviation from that, and perhaps have a river meeting at Reading or somewhere on the river.

Mr. WILLETT: Reading is easier for most of us to get away from. We had two very successful river meetings, and the ladies enjoyed them. Perhaps you will leave it to the President, Secretary, and Treasurer to fix it up.

A MEMBER: Don't forget there will be three Peace days in July.

Mr. WILLETT: We can either carry it forward or postpone it a week, so that it does not clash.

The CHAIRMAN: Perhaps it would be as well to have a jollification on one of the Peace days. But if you wish we will put it off to a week before or a week after.

*Defaulters.* Mr. WILLETT: I was instructed to write to two members, one of whom has not paid his entrance fee, and the other his subscription. I wrote to both—one sent a cheque, the other no reply. I take it we have your permission to strike him off.

The CHAIRMAN: According to the rules of the Association, if a member has not paid his entrance fee for six months he ceases to be a member.

Mr. WILLETT: As we are getting back to normal times, have I your permission to bring forward the names of those in arrear up to date—some of the men have been serving.

The CHAIRMAN: Very few veterinary surgeons have as yet been demobilised.

Mr. WILLETT: Is it your wish then to leave them over until the end of 1919.

A MEMBER: Yes.

The CHAIRMAN: In the Report of the Council of the Royal College of Veterinary Surgeons there is a recommendation from the General Purposes Committee that a circular letter be sent to all the local Veterinary Medical Associations. We have not had this letter yet, but by the time we get it, it will be too late to do any good. I thought the matter should be brought up to-day so that we can deal with it in accordance with the wishes of the Royal College in this matter. I take it that it means we should approach Members of Parliament and ask them to help us with regard to representation on this Bill. Perhaps Sir Stewart Stockman will give us his views on the matter.

The meeting resolved itself into Committee to consider this matter.

Upon the meeting being resumed it was resolved, that a resolution be sent to each Veterinary Society, the Board of Agriculture, and the Council of the R.C.V.S.,

upon this subject and the wording of same to be left in the hands of the President, Secretary, and Major Simpson, and the Secretary was instructed to forward the same to above-named bodies.

#### LESIONS IN THE DIAGNOSIS OF SWINE FEVER.

By ESMOND BROWN, M.R.C.V.S. Board of Agriculture.

Mr. President and Gentlemen,—When on Monday evening I received a copy of the agenda of this meeting I discovered that No. 5 was to be a paper on "*Lessons in diagnosis of swine fever.*" Now, the title I thought I had given in my letter to our Secretary was "*Lesions in the diagnosis of swine fever.*" No doubt the defects of my handwriting are responsible for the variation, and I hope that you do not suspect me of claiming the right to stand up before you as a pedagogue whose object is to deal out instruction.

It is not my intention to teach. Swine fever *has* taught me one lesson, and that is that it is not wise to be dogmatic over the questions of its diagnosis.

Any member of our profession who has, as part of his work, to deal with the diagnosis of swine fever is at times inclined to doubt whether the lesions are really very reliable guides. He gets cases where he finds lesions which appear characteristic, but where other evidence is against swine fever being present. At other times he finds all the other characteristics of swine fever, but no typical lesions. The discovery that in swine fever the actual element of contagion is an ultraviolet virus, and the relegation to a secondary position of the swine fever bacillus, or *Bacillus cholera suis*, naturally raised doubts as to whether the lesions were as reliable a factor in diagnosis as had previously been thought. In formal discussion, at any rate, the suggestion is sometimes thrown out that the value of the lesions in diagnosis is very much weakened, because of the possible existence of agents other than the ultra-visible virus which will prepare the ground, so to speak, for the swine fever bacillus to get to work.

In spite of these doubts, the consideration of large numbers of outbreaks of disease in swine, occurring over long periods and under diverse conditions, and the consideration also of the results of numerous experiments, has led to the acceptance of the view that there is a specific febrile contagious disease of swine, caused by an ultra-visible virus giving rise to fairly characteristic though varying clinical symptoms, and associated with the formation, in the majority of instances, of recognisable lesions; and further, that the occurrence of such lesions except as the result of an attack of swine fever is so rare that it may be almost disregarded.

The question as to whether the bacillus cholerae suis can set up lesions "on its own," or with the help of anything other than the ultra-visible virus of swine fever, is one for further observation and research, but from the practical point of view for present day diagnosis, I think that it is well not to attach too much importance to it.

The lesions will remain our best guide, in spite of their admitted shortcomings, until something better is given to us in the shape of an easily applied reliable test, and so far as I know nothing practicable in that direction has as yet been formulated. I do not mean to claim that swine fever can invariably be diagnosed by the evidence of lesions alone. In this disease, as in most others, every available relevant factor should be considered before a decision is made.

I will now proceed to a description of the principal lesions associated with swine fever; I shall also refer to a few lesions which have, I believe wrongly, been put forward as supporting a diagnosis of swine fever, and in addition shall call your attention to one or two normal anatomical peculiarities which are occasionally mistaken for swine fever lesions.

In some acute cases of swine fever the lesions are of a very vague character, and possess small diagnostic value. There may be little beyond slight congestion of mucous membranes and of some groups of lymphatic glands. Cyanosis of the ears and other parts of the skin is sometimes present without there being any other lesions.

Further up the scale come such lesions as petechial hæmorrhages in various parts of the body, severe congestion of mucous membranes of the stomach and intestines and œdema of the intestines.

The most characteristic lesions of swine fever, however, are the necrotic ones, namely the circumscribed areas of necrosis called swine fever ulcers, and the diphtheritic lesion which appears as a film on the surface of the mucous membrane, the film when detached by washing and manipulation leaving a roughened surface indicating some necrosis of the underlying membrane. I shall further describe these lesions in referring to their regional occurrence beginning with their distribution in the alimentary tract.

An attack of swine fever may lead to ulceration of the tongue, but ulceration of the tongue, though significant if clinical symptoms of swine fever are present, is not in itself very valuable evidence.

The mucous membrane of the pharynx frequently shows signs of ulceration, as also does that of the stomach. Ulceration of these parts may be due to swine fever, but I believe that as often as not it may be produced by other causes, and ulcerative lesions of these parts have about the same value for diagnosis as ulceration of the tongue.

The mucous membrane of the stomach often shows congestion. A certain degree of congestion of this membrane may be physiological, and due to digestive activities provoked by the presence of food.

Other common changes to the stomach are acute or chronic gastritis, shallow erosions of the mucous membrane, diphtheresis and ulceration as previously mentioned. Sometimes there are round button ulcers which are indistinguishable in appearance from those found in the large intestines in typical cases of swine fever. This last type of stomach ulceration I admit carries some weight, but on the whole it is well to beware of exaggerating the importance of stomach lesions in summing up the evidence for diagnosis. The stomach particularly is liable to inflammation and ulceration arising from causes other than swine fever.

Passing from the stomach to the small intestines, it should be noted that the opening of the bile duct into the duodenum may be expected to be found an inch or so away from the pylorus. The opening of the bile duct is large enough to stand the insertion of an ordinary match-stick, and more than once a match-stick has been inserted into the opening in order to indicate it as a swine fever ulcer. I must hasten to add that that error is not of common occurrence nowadays, any more than is the mistake of calling the continuation of the œsophageal mucous membrane over part of the gastric surface a swine fever diphtheresis, but as both these errors have at times been made I mention them as interesting curiosities rather than as being of serious import.

The mucous membrane of any part of the stomach and intestines may be bile-stained, but bile-staining is readily distinguishable from ulceration and diphtheresis by the fact that the structures of the membranes are intact and visible.

Genuine swine fever lesions in the small intestines are fairly common, especially in the last few feet of the ileum, and the large Peyer's patch in that position is frequently the seat of diphtheritic and ulcerative changes. Discrete ulceration is not so common in the small intestines as diphtheresis and necrosis affecting practically the whole of the mucous membrane of considerable lengths of the bowel.

There is a condition of the small intestine, *not* due to swine fever, which results in very great thickening of the bowel, but this thickening, instead of affecting principally the mucous and submucous coats as in swine fever lesions, is found to be in the muscular layers of the bowel wall. It is as though the muscular tissue has become hypertrophied in the attempt to overcome some obstruction further down. Usually the thickening terminates rather abruptly, and beyond the thickened portion the bowel wall may be thinner than normal, and showing perhaps a patch of necrosis of the mucous membrane accompanied by localised peritonitis. Sometimes there is actual perforation of the bowel wall at this point with escape of ingesta into the peritoneal cavity. This condition is not at all rare, it is probably due to some form of mechanical injury, and some cases at least appear to be due to injury to the bowel done during the performance of the operation of spaying.

Necrotic lesions, not due to swine fever, may be present in the small intestine as a result of umbilical or scrotal hernia with strangulation. The cause of such lesions ought to be apparent to anyone making the post-mortem examination, and the evidence of peritonitis is to be noticed both before and after the intestine has been removed from the body.

As a general rule, necrotic lesions of the intestines, when accompanied by peritonitis, do not point to the presence of swine fever, though exceptionally very severe chronic lesions of swine fever may eventually cause peritonitis by extending through the coats of the bowel to the peritoneal surface.

Intussusception of the bowel may be mentioned as causing necrosis—I should hardly call this, or eversion of the rectum, a swine fever lesion, but both these seem to crop up with fair frequency amongst pigs when other evidence shows clearly that swine fever exists, and the most obvious reason for this is that the disturbed state of the intestine due to swine fever favours intussusception and eversion.

I must now leave the small intestine and take up the catalogue of lesions as they appear in the large bowel. The ileo-cæcal valve, the cæcum itself, and the first part of the colon are the favourite seats of swine fever lesions, and it is here that the most satisfactory post mortem evidence of swine fever is to be looked for.

Besides the usual acute lesions, congestion, and petechial hæmorrhages, one may come across larger submucous hæmorrhages up to half-an-inch or more across, circular in outline, and these hæmorrhages may show considerable depth or thickness. In some instances such comparatively large submucous hæmorrhages are fairly numerous, and often some necrosis or diphtheresis may be found on their surface. It is likely that such hæmorrhages would have developed into typical circular ulcers if the subject had lived longer.

œdema of the wall of the cæcum and part of the colon is a common lesion of swine fever, and I think that it is, next to typical ulceration and diphtheresis, of the highest diagnostic value. When I claim this I do not refer to slight œdema, but to a condition in which the thickness of the bowel wall is increased to many times the normal, and in which the jelly-like œdematous tissue fairly quivers on the piece of bowel being taken in the hands and shaken. This severe œdema is more often found in large and middle-sized pigs than in very small ones, usually signifies a virulent type of swine fever, and in some series of connected outbreaks it is the most constant lesion; sometimes as the only change present and at other times accompanied by hæmorrhages and ulceration.

Swine fever ulceration of the large intestine may give rise to a variety of appearances. The ulcers usually regarded as most typical are those with a circular outline. These may be of any size up to that of half-a-crown;

exceptionally, a regular circular ulcer up to the size of a five shilling piece may be found. The surface of the necrotic tissue is generally raised above the level of the surrounding mucous membrane, and it often shows concentric sizes. The colour may be anything from dirty white or yellow to greenish or brownish black. If the animal lives long enough the necrotic tissue starts to separate from the normal at the edge, leaving a slight gap. Then the necrotic portion or button is shed and cicatrization of the ulcer takes place. The surface of the ulcer is then below that of the surrounding membrane and the cicatricial tissue contracting, the normal membrane becomes drawn in a little sometimes irregularly, presenting a puckered appearance. The depression may become entirely obliterated by the formation of the cicatricial tissue, but the cicatrix can be detected by the fact that the intestinal glands are not replaced and by the surface of the scar giving a harsh impression on palpation. It has not the velvety feel of normal mucous membrane. Often the scar tissue shows a great tendency to crack when the bowel is manipulated on post mortem.

Other shapes besides the circular are often found. At the edge of the ileo-caecal valve crescentic ulcers are quite common, and irregular ulcers of all sizes may be present in the caecum and colon. Sometimes the surface layers of the mucous membrane become necrotic over almost the whole area of the caecum and a good deal of the colon. Amongst this extensive necrosis, circular or irregular islands of normal membrane may be seen. If the necrotic tissue is shed and cicatrization takes place, these islands appear as elevations surrounded by scar tissues.

Sometimes the changes, although spread over a wide surface do not result in a wholesale necrosis and shedding, but lead to a thickening and corrugation of the mucous membrane, with necrotic points and streaks which may become cicatrized. The appearance in some instances may be compared with that of the bovine intestine in a case of John's disease, though the corrugations in swine fever are usually coarser.

Sometimes the principal lesion of swine fever present is a shallow ulceration, a thin layer of necrotic tissue having been shed. Often this shallow ulceration is extensive, is irregular in outline, and may show at the junction with the normal membrane a distinct black line. This type is often referred to as "black edged ulceration."

*Diphtheresis* may be found in any part of the caecum and colon, and often affects several feet of the intestine. In many cases it is present in the caecum, then eighteen inches or so of the colon are free, and following this clear interval a length of colon shows pronounced diphtheresis. Sometimes the only gross lesions of swine fever present is diphtheresis of the middle loops of the colon.

Adherent bowel contents may at first sight look like a diphtheresis, but, after washing, the material comes away more easily than a swine fever diphtheresis, and the underlying membrane, though it may be mottled through irregular pressure, does not show abrasions or necrosis.

There is a lesion of the large intestine sometimes called "chamois gut," which may involve several feet of the bowel. The wall of the intestine is rather thinner than normal, the inner surface is dirty yellow in colour, and is harsh and leathery in appearance. In places there may be evidence of a deeper necrosis. I am not certain as to what position this lesion should take in the diagnosis of swine fever. I have known it to occur when other evidence of the existence of swine fever has been lacking, and when subsequent enquiries at intervals over several weeks have failed to bring to light any further evidence. On the other hand it sometimes turns up in outbreaks where there is more typical evidence of the existence of swine fever. It is perhaps a lesion which

should always arouse suspicion, but one which does not justify a positive diagnosis unless the supporting evidence is strong.

#### SWINE ERYSIPELAS.

An attack of swine erysipelas may produce a kind of diphtheresis.

This usually has a smooth surface, and is bright in colour, and the mucous membrane looks as though it had been smeared with yellow or green oil paint.

The question of the existence of swine erysipelas may be settled by laboratory methods, but apart from that the usual lesions of swine erysipelas may be found elsewhere than in the bowels. If there is other evidence of the existence of swine erysipelas the appearance which I have just mentioned should be looked upon as furthering a diagnosis of erysipelas rather than as pointing to swine fever. At the same time, intestinal lesions due to swine erysipelas do undoubtedly add much to the difficulties connected with the diagnosis of swine fever.

I will now take up the question of tubercular ulceration of the intestines. It is sometimes assumed that when a pig is the subject of extensive tuberculosis any intestinal ulceration must be due to tuberculosis and not to swine fever. Sometimes ulceration of the intestine is diagnosed as tubercular on account of the crater-like shape. In individual cases the matter may be settled by bacteriological and histological examination. Bacteriological examination alone may mislead in cases where, apart from the ulceration, there are extensive tubercular lesions of other parts. I shall not go further into the methods by which individual cases may be decided, because this paper is written mainly from the viewpoint of the man who makes post mortem examinations in the field, without elaborate accessories.

Tubercular ulceration of the intestine of the pig is not of common occurrence. Swine fever ulceration is. Tubercular ulcers when present are more likely to be found in the small intestine than the large, while the reverse is true of swine fever ulcers. The crater-like shape of some ulcers may make one think of tuberculosis, but a deep swine fever ulcer, after the greater part of the necrotic tissue has been shed may show a comparable appearance.

I think I have said enough to suggest that when ulcers are present in the large intestine of a pig, even though the animal may show undoubted tubercular lesions elsewhere, it is well not to dismiss the case as one of tuberculosis only without considering very carefully the possibility of the co-existence of swine fever.

I have not much more to say about the caecum and colon, except to mention a few points which should be borne in mind when one is making a post-mortem examination on an animal suspected of being affected with swine fever.

Around the ileo-caecal valve are a number of intestinal glands or follicles opening on to the surface of the mucous membrane. These often become plugged with a cheesy material, and the mouths of the glands with the ends of the plugs showing certainly bear, at first sight, some resemblance to swine fever ulcers. The plugs can, however, be easily pressed out with the thumbs. The gland mouths may then appear rather gaping, but neither the plugs nor the gaping mouths have anything to do with swine fever.

An inch or two away from the ileo-caecal valve are to be found patches of intestinal glands, generally more or less circular in shape, and the patches are usually slightly raised above the surrounding membrane. In cases of swine fever they are often involved in necrotic lesions, but they are not themselves lesions, but normal structures.

Scattered up and down the large intestine are numerous solitary glands or follicles, and these may become

elevated and be plugged with cheesy material in the same way as the larger glands around the ileo-caecal valve, and they are often especially prominent in the latter part of the colon and in the rectum. I do not think there is any association between swine fever and the prominence of these glands.

Occasionally the solitary follicles show a little necrosis around their mouths. This may be due to swine fever, sometimes it is seen in cases of swine erysipelas, but such slight necrosis may occur independently of either disease.

If a pig has been dead for some time before examination is made the mucous membrane of the intestine may be discoloured by post mortem change, and sometimes gas bubbles are formed under the membrane. Allowance should be made for what may have happened after death, when considering the appearance of the intestine.

In many pigs the intestinal mucous membrane is naturally pigmented, but the pigmentation ought not to be mistaken for a swine fever lesion.

I must ask for your forbearance for few moments longer while I mention a few lesions to be found in parts of the body other than the alimentary tract.

Cyanosis of the skin I have already referred to. It is not peculiar to swine fever.

Areas of necrosis may be found in almost any position on the skin. Those which bear most resemblance to swine fever ulcers are usually in the under part of the body, where the skin is thinner. The skin inside the prepuce sometimes shows quite a crop of small ulcers. Skin ulceration may sometimes be due to swine fever, but it has not much diagnostic value.

In acute cases of swine fever there are often petechial hæmorrhages on the epiglottis, in the kidneys, and in some cases in the bladder also.

With regard to hæmorrhages, particularly petechial hæmorrhages of the epiglottis and larger hæmorrhages in the heart wall, it is worth remembering that slaughtered animals may show a few recent hæmorrhages irrespective of any diseased condition, the hæmorrhage occurring in the death throes.

Sub-endocardial hæmorrhages are very commonly to be found in animals slaughtered by bleeding.

Congestion of the lungs, and pneumonia, the latter often of a dry necrotic type, are frequently to be found in pigs affected with swine fever. Necrotic pneumonia should always rouse suspicion, though if a number of pigs are available for post-mortem examination and all show pneumonia of this type without any intestinal lesions it may be safe to assume that swine fever is not present, but even then it is better that any surviving pigs should be kept under observation for a time.

That concludes my account of the lesions. To keep the paper within limits I have had to cut out many details, and it has been impossible to give a description of the appearances of the manifold forms in which swine fever may declare itself in the way of lesions.

My efforts will now be supplemented by a selection of lantern slides prepared by Mr Norman, Chief Laboratory Assistant here. Also, in the Museum, there are a number of preserved, and more or less fresh specimens which will be available for your inspection if there is time after the more formal part of the meeting is over.

At the termination of his paper Mr. Brown gave an excellent display on the screen of many lesions which he had mentioned in his paper.

The PRESIDENT proposed a most hearty vote of thanks to Mr. Brown for his very excellent paper and illustrations, and that the discussion should be deferred un-

til our next business meeting, as in the short time left at our disposal, full justice could not be rendered.

The SECRETARY seconded, and it was carried with acclamation.

Sir Stewart Stockman then gave a most interesting cinematograph show, of horses affected with parasitic mange, and their treatment with the spray. Also, some cases of "Scrapie" in sheep. This disease is prevalent in the North country, but Sir Stewart informs us that it has not existed in the South for 100 years.

This concluded one of our most enjoyable of meetings, and the President thanked Sir Stewart on behalf of the Society for his kindness in inviting the Society to the laboratory, and the very interesting subjects which he had illustrated on the screen.

J. C. COLEMAN, Hon. Sec.

## VETERINARY POLITICS.

*To the Editor of "The Veterinary Record."*

Sir,—The contents of your "Correspondence Columns" during the past few weeks I have read with interest, and although I may be severely criticised for entering into the discussion, being a student, I will excuse myself on the plea that the Public Schoolboy has been attacked, and intends to retaliate.

Mr. Squair asks:—"How many public schoolboys have the courage to enter the profession? or having entered it, have the 'guts' to become successful veterinary surgeons?" He is of opinion that there are very few. I have summoned up enough courage to endeavour to enter it, and could enumerate quite a number of others, including a brother, who have taken the degree.

I consider that to be a successful veterinary surgeon, financially and socially, a man requires to be well-educated and have plenty of tact, as he is brought into contact with so many different classes of humanity, but, he should bear in mind that to be pleasant with a man it is unnecessary to adjourn to a public-house and make yourself 'cheap.' That is how so many lose any respect that might be due to them. Also it is desirable always to remember that "Familiarity breeds contempt."

There are two classes of public schoolboys—Gentleman and Snobs. The latter will never be successful as doctor, barrister, veterinary surgeon or anything else; the former, if he is keen enough to undertake veterinary surgery will put up a jolly good fight to make it a success.

I feel confident "Dagonet" need not fear that veterinary surgeons will be done without if they ask for a reasonable remuneration for their services. Insurance companies may dispense with V.S. Reports, but time will bring them to a more reasonable state of mind if what I have seen is the case generally.

Undoubtedly, if members were to combine, and not endeavour to "cut one another's throats" they would receive greater respect, and at the same time be able to fight the "Patent Medicine man."

There is no doubt in my mind that in order to establish such a brotherhood every Veterinary School should have its Students' Club where social intercourse might be cultivated by members of the different years, and this should at the same time afford an opportunity to the less fortunate ones to self-educate themselves, and thus raise indirectly the future standard of the profession.—Yours faithfully,

L. ST. BEL GOLLEDGE, Class "D"

Royal Vety. Coll.: N.W.

May 5th.

# ROYAL COLLEGE OF VETERINARY SURGEONS FELLOWSHIP DIPLOMA.

A meeting of the Board of Examiners for the Fellowship Diploma was held at the College, 10 Red Lion Square, London, W.C., on Saturday, May 10th, 1919. Four entries were received and the following candidates were successful:—

## *New Regulations.*

Capt. Thomas Michael Doyle. Tropical Medicine. Thesis: "Piroplasmiasis." Examiners:—Capt. J. T. Edwards, B.Sc., and Professor J. Macqueen.

Capt. George Church Lancaster. Veterinary Surgery. Thesis: "Gunshot Wounds in Animals and their Treatment." Examiners:—Professor J. Macqueen, and Mr. J. Malcolm.

## *Old Regulations.*

Capt. Alexander Taylor, M.A.; Examiners:—Professor J. Macqueen, Messrs. J. Malcolm and W. Woods.

W. J. MULVEY, Chairman.  
FRED BULLOCK, Secretary.

## **Personal.**

Mr. P. G. BOND, M.R.C.V.S., at Plymouth Institution recently gave two lectures on "Men of the South Hams." The first dealt more particularly with those who in the past had played an important part in local and national affairs, while the second was devoted to South Hammers who had rendered noble service in Empire building.

The lectures were much appreciated by large audiences and were illustrated by fifty lantern pictures. Mr. Bond who has a wide knowledge of most matters appertaining to the history of the West of England, presented to the Institution an album of pictures of the many ancient houses he had described.

Mr. G. GAIR, J.P., M.R.C.V.S., Conon Bridge, has been elected on the Ross-shire Education Authority (Mid Ross Division). He headed the poll of the seven members elected. The successful candidates included two Medical practitioners, a Minister of Religion, two Proprietors, and a Farmer. There were eleven unsuccessful candidates.—*The Ross-shire Journal*.

## **Deputation of V.M.A. to the Chief Secretary for Ireland.**

The second deputation, representing the North of Ireland Veterinary Medical Association, consisted of Mr. J. Ewing Johnston, M.B.E., M.R.C.V.S. (president of the Association); Mr. F. W. Emery, F.R.C.V.S.; Mr. J. A. Jordan, M.R.C.V.S.; Mr. Thomas M'Guinness, B.A. M.R.C.V.S.; and Mr. J. J. Ross, M.R.C.V.S.

In the course of their speeches the members of the deputation pointed out that as an Association they felt the Ministry of Health Bill was one which vitally affected the profession, and that the duties devolving upon them as veterinary officers would be of an onerous and responsible character. It had now been conclusively proved that disease had been conveyed from the farmyard to the consumer in consequence of the ailment from which the animal suffered while alive, and it had also been proved beyond question that many serious forms of disease, including tuberculosis, anthrax, etc., which had manifested themselves in our large industrial centres, had been traced to places of production. In the past the public health authorities had endeavoured to the

best of their ability to cope with such matters, but it had now been admitted that the services of veterinary officers, with their technical knowledge and experience, were necessary in order that such forms of disease might be traced to their origin and the most up-to-date methods adopted to eradicate them. To this end the Association recognised that it would be necessary to entrust to veterinary officers appointed under the Bill the following duties:—(1) The inspection of dairies and cowsheds; (2) the examination of animals with, when necessary, the application of scientific tests for disease; (3) the examination of animals intended for the food of man prior to slaughter; (4) to assist in tracing diseases and in elucidating points of doubt and difficulty in all cases in which it may be presumed such have arisen from or through animal sources; (5) meat inspection; and (6) to control well-equipped and soundly-supported laboratories established for research and experimental work in connection with this special service.

The deputation pointed out that in order that the foregoing duties might be efficiently performed it was desirable that at least one veterinary officer who should devote his whole time to the duties should be appointed by each county council, and under those conditions the health of a community would be safeguarded and the dangers of disease reduced to a minimum. Also, having regard to the very prominent part the profession would have to take under the Act, it was thought it should have at least two representatives on the Irish Public Health Council, and further, that clause D of the Bill should be amended so as to expressly provide that one of the members of the Council should be a member of the Royal College of Veterinary Surgeons.

It was submitted that no Ministry of Public Health could be efficient or complete without an independent veterinary section upon which the Minister could rely for correct information and guidance, and to which matters relating to animal disease should be referred. There were numerous diseases of man and animals that were so closely related in their causation that for their elucidation the most cordial association of the medical officer and the veterinarian was essential.

On the subject of the inspection of meat and dairy herds it was claimed that for the efficient performance of these duties it was imperative that the veterinarian should have the active control and complete discharge of services connected therewith—working, of course, in co-operation with the medical officers of health. Generally speaking, at the present moment this county was practically without a proper system of meat or dairy inspection. Some places in Ireland where there was no system of meat inspection constituted a grave menace to centres such as Belfast, where, notwithstanding the strictest surveillance, it was possible for dishonest traders under cover of darkness to surreptitiously deposit diseased carcasses in different parts of the city. The abolition of all private slaughter-houses, the establishment of public slaughter-houses in urban and rural districts under the administration of the County Council, the adoption of a uniform system of meat inspection, and the appointment of whole-time veterinary meat inspectors would, it was claimed, go far to remove this evil.

In regard to the milk supply, it was urged that the Ministry of Health Bill provided an opportune moment for putting into effect some scheme for the safeguarding of the public health by a well organised control of the milk supply. In order to ensure a pure milk supply the deputation advocated the licensing of every milk vendor, whether wholesale or retail, and that every applicant for a licence to trade in milk or its derivatives should be compelled to fulfil certain well-defined conditions. It was felt that they ought at least to insist that the con-

ditions pertaining to the supply of milk were as stringent as those governing the manufacture and sale of intoxicants.

The deputation received a favourable and sympathetic reception from the Chief Secretary, who informed them that the Ministry of Health Bill was going forward. He urged the members to proceed with propaganda work, and said he was satisfied that they would obtain recognition.—*The Northern Whig*.

### ELECTION ADDRESSES.

#### *To the Members of the Royal College of Veterinary Surgeons.*

Gentlemen,—In issuing this appeal I am not following the stereotyped custom of a host of promises usually set out in an Election Address, but to state.

I have been nominated by the Yorkshire Veterinary Medical Society for re-election, after serving 12 years on the Council R.C.V.S., and as a member of the Registration, Finance and other important Committees.

I am essentially a practitioners' representative, am conversant with the needs and reforms beneficial to the profession, and will, when finance permits, lose no time to secure them.

I consider your Council during the last four years has conducted the business of the profession with ability and economy.

If you do me the honour to re-elect me, I can assure you of my best endeavours to justify your confidence.—Yours faithfully,

Westfield House, SAMUEL WHARHAM.  
Leeds, 12 May, 1919.

#### *To the Electors of the Council R.C.V.S.*

Gentlemen,—Last year, nominated at the last moment, I received a gratifying amount of support and I again solicit your votes. Now, as then, I consider Finance, Parliamentary representation, and greater publicity of our proceedings are matters of first importance. Reports in the press tell us that medical men are striving for more direct parliamentary representation. If important for them it is surely a hundredfold more important for us. We have no representation, no one fully conversant to represent our views across the floor of the Commons, the one place that obtains publicity and demands attention. Frequently we notice men of our profession complaining of the social standing of the profession, "That it is little thought of" etc. Individually I think it is largely personal. Collectively we cannot hope to obtain this unless we obtain greater publicity and the public educated to the activities and importance of the profession for the public good. Our Military tribunal should continue to press for the demobilisation of our men. Surely hundreds could now be allowed to return to their homes.

*Education.* The standard for admission should tend to rise. Subjects of no use to the practitioner

eliminated and others of importance substituted in the curriculum.

*Representation.* The present Council is not representative of the profession. I am in favour of representation for the schools, Army, Board of Agriculture, and also district representation. Councilmen of the latter class by attending the Association meetings of their districts would be in constant contact with the views of their electors and would more surely be their representatives. It would also, I am confident, bring a larger number of men to the membership of the Associations, and arouse that enthusiasm now largely dormant. "Fees," "appointments," "the wants of the general practitioner" etc., would then be more advantageously discussed, and resolutions passed, for the guidance of their representative.

Councilmen elected should be pledged to a regular attendance and if, unhappily, that became impossible, should forthwith resign.

55, Southgate St., J. B. TUTT, F.R.C.V.S.  
Winchester, May 10/19.

### ROYAL COLLEGE OF VETERINARY SURGEONS

*To the Editor of the "Veterinary Record."*

10, Red Lion Square, S.W. 1.

Dear Sir,—On the instructions of the President, I am to remind members returning to civil life of the necessity of notifying me of their new address, in order that any necessary correction may be made in the Register. This is especially important in view of the forthcoming issue of voting papers which will be despatched on May 21st.—Yours faithfully,

FRED BULLOCK, Registrar.

### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919:—

Allen, H., Major, R.A.V.C.	£1 1 0
Foster, A. N., Major, R.A.V.C.	1 1 0
Skelton, S. H., Capt. R.A.V.C.	1 1 0
Taylor, R. C., Colchester.	1 1 0
Previously acknowledged	739 15 10

May 13. £743 19 10

### ARMY VETERINARY SERVICE.

*Extracts from London Gazette*

WAR OFFICE, WHITEHALL, May 7.

REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Temp. Capt. W. B. De Vine relinquishes the actg. rank of Maj. on ceasing to be empld. as D.A.D.V.S. (Apr. 10).

May 9.

Capt. to be actg. Maj.:—J. J. G. Keppel, Spec. Res., whilst holding the appt. of D.A.D.V.S. (Feb. 12); P. J. Malone (March 5.)

Capt. C. D. M. Buckley, M.C., M.B., relinquishes the actg. rank of Maj. on reposting (March 27).

May 10.  
Temp. Capt. H. G. Simpson relinquishes actg. rank of Maj. (April 19).

Temp. Qrmr. and Lt. G. P. White, from Gen. List, Infy., to be temp. Qrmr., with the rank of Lt. (Feb. 26, 1918).  
Temp. Qrmr. and Lt. O. Preston, to be Capt. under Art. 330. R. Wt. for Pay and Promotion (April 28).

May 12.  
Capt. T. A. Dobie, Spec. Res., to be actg. Maj. (Feb. 8).

May 13.  
Temp. Capt. E. J. Burndred relinquishes the actg. rank of Maj. on vacating the appt. of D.A.D.V.S. (Apr. 23).

#### TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

May 7.  
Capt. J. E. L. Still to be Maj. (April 10).

May 8.  
The notification regarding Capt. (now actg. Maj.) R. E. Beilby, which appeared in the *Gazette* of April 11, is cancelled.

May 9.  
Capt. (temp. Maj.) J. Gillies, R.A.V.C. (T.F.), relinquishes the temp. rank of Maj. on ceasing to be empld. (Apr. 1).

May 12.  
Capt. (actg. Maj.) W. K. Barron relinquishes actg. rank of Maj. on ceasing to be empld. (March 20).

Capt. (actg. Maj.) G. H. Farrell is retired, having attained the age limit (May 13), and retains rank of Maj.

Capt. (actg. Maj.) C. Hartley, R.E.C.V.S., relinquishes actg. rank of Maj. on ceasing to be empld. (April 5).

Capt. (temp. Maj.) C. E. Neill relinquishes temp. rank of Maj. on ceasing to be empld. (April 10).

Capt. (actg. Maj.) J. J. Ridley relinquishes the actg. rank of Maj. on ceasing to be empld. (March 29).  
Capt. (actg. Maj.) J. H. Wright relinquishes actg. rank of Maj. on ceasing to be empld. (April 5).

The War Office announces the following casualties:—

\* \* \* \*  
Died.—McMAHON, Capt. B., R.A.V.C., attd. R.F.A.

#### An experiment in Sheep Breeding.

A Victorian (Australia) breeder who raised sheep for mutton began the plan of setting apart for special attention the ewes which yielded twins. In all flocks there is a percentage of ewes which are unusually prolific, and he worked on that fact. His experience has been that the ewes, with sufficient food, were able to support in the young stages two lambs as well as one. The result of the scheme has been remarkable. Before he embarked upon it his lambing percentage was 89. The next year, after culling, it rose to 104, and in the third year to 144. He is so satisfied with his project that he has mapped out a course to apply the principle to rams—that is, selecting the sires which are themselves descended from prolific mothers. Breeders all know the value of the principle of selecting in the dairy herds, and there is no reason to fear the results when applied to other live stock. This breeder expects that before he has done he will develop a flock which will give him a lambing percentage of at least 200 per 100 ewes. That, he thinks, would be a safe point at which to halt.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1611.

MAY 24, 1919.

VOL. XXXI.

## THE MAINTENANCE OF THE REGISTER R.C.V.S.

Last week we printed an official letter from Mr. Bullock, our Registrar, written "on the instructions of the President," reminding members returning to civil life of the necessity of notifying him of their new addresses. The issue of voting papers is mentioned as a special reason for the appeal; but there are other and much less temporary ones. Considering the number of men already demobilised, the probability of others soon to follow, and the well-known carelessness of members regarding changes of address, the Registrar seems likely to have a more troublesome year's work than he has yet had. In normal times, he cannot bring the Register to its maximum of possible accuracy without some help from the members. That help is more necessary now than ever, and many whose own addresses are not in question may be able to give it. It should not be forgotten that the Statutory evidence of a man's qualification is the presence of his name on the Register.

## VETERINARY SURGEONS IN PUBLIC LIFE.

A notification that Mr. G. Gair, of Conon Bridge, Dingwall, who is already a J. P., has been elected upon the Ross-shire Education Authority, appeared in our pages last week. He headed a list of seven successful candidates, which included two members of the medical profession and one of the clerical. This is another illustration of the not sufficiently recognised truth that, whenever a veterinary surgeon is willing to enter the public life of his district and is capable of discharging the duties, his profession is no bar to his entrance. The truth has been proved often enough all over the country; but not so often as it would have been had not members generally been so lukewarm in these matters. There is no doubt that we have ourselves largely to blame for the slight part we have hitherto played in local public life. Admittance to it depends upon a consensus of local opinion as to the individual's fitness for the duties—that is the one test. A veterinary surgeon has as good opportunities of becoming widely known in his district as any man; and, if he is also favourably known, a share in its public life is at his choice. One of the just reproaches of the profession to-day is that the choice of the great majority of us has always been to keep out of public life and work. There are many who could enter it at any moment; but while nearly all refuse it the profession can hardly play the part in our national life that it might do. All honour to the few pioneers like Mr. Gair, who set a good example to their less public-spirited colleagues,

## THE VALUE OF READING.

The main object of most men in attending courses of instruction at a Veterinary College is to obtain sufficient knowledge to satisfy the examiners. Many men do very little study after receiving the diploma, and men have been met who boasted that they had not opened a book since they left college, and others have admitted that they did not read because they could learn nothing from books, as most of the writers were not practical men.

The term "practical man" is one very difficult to define, but "practical" is certainly not synonymous with well informed. The practical man may handle his patients well, and attend to them in what he considers the one and only manner, and he may have learned much from experience; but what is all this worth if he has not compared his experience with that of others? No one considers he knows all that is to be known concerning the veterinary art—this would be the height of presumption—and if such a person does exist he is to be pitied.

An address was given to students by a professor on the true aims of education, and in that address the central idea was that students and others had to "learn how to learn." That phrase has stuck to me, although it is nearly twenty years since I heard it used first.

There is very little to be gained by taking only a narrow survey of any subject. Our outlook and our reading must essentially be as wide as possible. Some men—more especially during war—are extra hard-worked and have very little time for reading. It does not depend upon the amount read; what really matters is the amount assimilated, and that left to give food for thought. It is a great mistake for a professional man to stick only to literature pertaining to his profession, as much can be learned in works dealing with travel, biography and history. Fiction also serves to refresh the tired mind. Veterinarians possess a good secondary education, and it behoves us to continue to build on the foundation laid during our school days.

A veterinary surgeon, known to the writer, who was highly successful in practice and in financial affairs, attended to his practice from 7.30 a.m., to 5 p.m., and his leisure was occupied with the newspapers and love stories. There is an old couplet:—

"Ease without occupation is not rest"

"A mind quite vacant is a mind distressed."

Wide reading has very many advantages. Much information that is of considerable interest and importance to student and practitioners does not appear in professional papers, and one requires to read many and various publications to keep up-to-date.

Those who have a knowledge of languages derive considerable benefit from the study of foreign textbooks and papers. Many more veterinarians in this country should read American veterinary papers. The advertisements that appear in them will repay close perusal. What strikes one most in reading the American veterinary publications is the way in which the meetings of association are conducted. The American Veterinary Medical Association has nearly 3000 ordinary members and there are 28 honorary members, four of these being well known Britishers namely, Hoare, Hobday, M'Fadyean and Stockman. There is no way of telling from the reports how many British graduates are members.

A few notes on how the Americans conduct their meetings may be of interest. The following is a brief summary of a meeting held in January 1918, at Ithaca. The subjects for discussion on the first day were:—

The veterinarian and conservation.

Lesions in spavins and their significance, (illustrated by lantern slides).

Digestive action of the mouth secretion of the horse. Garbage feeding, and the care of garbage fed swine. The work of the Bureau of Animal Industry and the War.

Treatment of retained placenta.

Retained placenta and its consequences.

Work of the State food Commission.

Live stock production and the veterinarian.

In the evening a smoking concert was held. The papers on the second day were:—

Tuberculosis of the generative organs.

The actual cautery for chronic inflammation of tendons and tendon sheaths of the leg of the horse.

The organisation of a Veterinary Corps for the National Army.

The economic and military necessity of an Army Veterinary service.

At all meetings there are clinical demonstrations and the following is a list of the cases shown at a meeting.

- (1) A black mare affected with high ringbone on both fore limbs was presented and double median neurectomy was performed.
- (2) A fibroma at the point of shoulder was removed from a black gelding.
- (3) A bitch was presented for oophorectomy. The hyoscine-morphine-cactin anæsthetic was used.
- (4) A pig with prolapse of the rectum and a sow with hernia were also presented.

The clinic occupies the whole afternoon of the second day.

We have nothing similar to that here, and the above example of an American veterinary meeting is given to show the value of reading. Had we not read of these things, we probably would still have been in utter ignorance of them.

Reading is of immense value to those whose duties include the writing of reports. Books are the direct source of instruction, solace, wisdom and recreation; they are the food of the mind and the spirit.

The following wish, written in the 16th century expresses the sentiments of the writer of these notes.

"May I a small house and a large garden have,"  
"And a few friends and many books."

"LAMANOHA"

#### A SIMPLE METHOD FOR THE DETECTION OF SMALL PARASITIC WORMS IN THE FIELD.

The writer has drawn attention\* to the unnecessary prevalence of worm infestation among young stock. Often a number of animals die before the condition is recognized. One reason for this is that many of the worms are too small to be seen readily by the unaided eye, especially when they are mixed with the contents of the stomach or intestines.

A simple method for the detection of some of these smaller worms is as follows:—Take up with a knife a scraping from the mucous membrane and spread it lightly as a thin moist film upon a piece of glass—window glass will do, but a microscopical slide is safer to handle. The smear should then be held up between the eye and the light when many of the worms can be seen as characteristic wavy, curved or straight lines, grey, greyish yellow or brownish red in colour, and tapering at one or both ends. The use of a pocket magnifying glass aids the detection of the worms. The smear can also be examined against a dark surface e.g., that of a bowler hat.

In the case of ruminants a good place to see the worms is under the folds of the abomasum.

The same method may be adapted to the examination of the faeces from suspected cases, but the parasites will be fewer in number and a longer examination will be necessary.

#### CLINICAL CASES.

By J. H. PARKER, Faringdon.

##### SCROTAL HERNIA.

*Subject:* Yearling Shire colt: cost 48 guineas as sucker last Malmesbury sale. Owner stated he was a bit full in scrotum when purchased, but thought it had disappeared. Cast him for castration in May and carefully examined him; could find nothing wrong, but warned the owner that bowel might descend when testicle was removed. Orders to risk it. Immediately the testicle (left) was exposed, small intestine followed. The colt kept heaving, and soon the left sac was full of bowel and up to the size of a child's head. We removed the testicle by actual cautery, carefully sealed up the blood vessels, sutured the operation wound. We then drew the skin up as tight as possible and darned up the scrotum with interrupted sutures as

\* *The Scottish Journal of Agric.*, Vol., ii No. 2, Apr. 19' p. 243  
*The North British Agriculturist* Feb. 20 1918, p. 117.

high as possible, and after making sure all the bowel was returned, put a wooden clamp on including skin and everything. The colt was allowed to rise, and commenced feeding. Two days afterwards a messenger came to say they thought the bowel had descended again, but it was only the swelling caused by the clam. Six days afterwards a post-card stated the colt was doing well, and the clam was coming off. It came off on the seventh day. On the ninth day a message stated the colt to be "all of a heap." I found that the hernia operation had been a success; but the colt had developed lockjaw, and he died two days afterwards, in spite of the fact that he had been drenched with disinfectants twice a day since the clam was applied.

#### PIPING.

Last November an urgent message came to see a cow "with yards of piping hanging from her behind," and he didn't know what it was, although he said the cow seemed alright otherwise. I went next morning, and found it had all come away, and that it was the small intestine of a sheep, about four yards, which she must have swallowed and passed right through her. It was very fetid, and on my arrival the ducks were tucking it into them with evident enjoyment.

#### THE CENTRAL VETERINARY SOCIETY.

[NATIONAL V.M.A.—SOUTHERN BRANCH].

A General Meeting was held at 10 Red Lion Square, London, W.C., on Thursday, May 1st, at 7 o'clock, Professor G. H. Wooldridge (President) in the Chair.

The following Fellows signed the attendance book:—Messrs. E. L. Stroud, J. Rowe, F. G. Samson, H. D. Jones, H. King, H. C. P. King, W. N. Thompson, J. W. McIntosh, A. E. Willett, J. Willett, R. C. Irving, W. R. Clarke, G. H. Livesey, P. W. D. Smith, W. F. Widden, W. Perryman, G. P. Male, and Hugh A. MacCormack. Hon. Sec.

Visitors: Capt. J. McAnulty, Vety. Corps, U.S.A., 2nd Lieut. J. J. Marten, Vety. Corps, U.S.A., Capt. J. B. Leitch, A.A.V.F., Maj. P. J. Simpson, R.A.V.C., Gilles de Kock and J. Bell.

*Minutes.* It was decided that the minutes of the previous meeting, which had not yet been published, should be taken as read.

*Correspondence.* The SECRETARY read letters from Messrs. J. B. Buxton, S. H. Slocock, and J. C. Coleman regretting their absence from the meeting. Also a letter from the Royal Sanitary Institute requesting the Society to send a delegate or delegates to their next meeting on July 28—August 2nd, at Newcastle-on-Tyne.

The CHAIRMAN said that Section (5) of the letter, referring to a conference of veterinary inspectors, was the section which was of particular interest to the Fellows as veterinary surgeons.

After discussion it was decided, on the motion of Mr. Willett, seconded by Mr. Stroud, that the consideration of the appointment of delegates to the Conference of the Royal Sanitary Institute should be postponed to the next meeting.

The CHAIRMAN reported to the meeting that the Council had decided to make a donation of Twenty Guineas to the Anglo-Franco-Belgian Relief Fund, and a donation of Two Guineas to the Victoria Veterinary Benevolent Fund.

The meeting then passed a vote of sympathy with the relatives of two Fellows of the Society who had recently died, Mr. Woodger and Mr. Heatley. A vote of sympathy with Mr. Foreman, who had recently lost his wife, was also passed. The Secretary was instructed to communicate the sympathies of the meeting to the relatives.

*Nomination.* Major Percy Simpson, D.S.O., was nominated for Fellowship and will come up for election at the next meeting.

#### FATTY FÆCES.

The RESIDENT invited Mr. Livesey to make a further statement with regard to the case which he had mentioned at the last meeting, of a dog which had been passing fatty stools.

Mr. LIVESKY announced that the dog in question had made an uneventful recovery, which he did not attribute to any drugs or treatment of his, beyond good nursing and sticking to the diet of meat and such food as Benger's Food, and the avoidance of fatty substances such as bread and margarine. He could not account for the illness; he did not know its cause, but he supposed it was caused by some temporary cessation of the action of the pancreas. If any further development of the trouble should occur he would report it to the Society, as he thought it an interesting case, the origin of which it was very difficult to explain.

#### "SOME OBSERVATIONS ON EQUINE INFLUENZA"

by Mr. G. P. MALE, M.R.C.V.S.

#### DISCUSSION.

Mr. THOMPSON, said he thought Mr. Male was to be congratulated on his most interesting paper. He would deal with the ten questions which Mr. Male had specially raised in their order.

The first head was the cause. He did not think many members could go further than Mr. Male had gone, because they were more or less in the hands of the pathologists, and the generally accepted theory at the present time was that it was due to an ultra-visible organism. That was the exciting cause. The pre-disposing causes, undoubtedly, were of some importance. Any cause, which interfered with the animal economy, subjects it to be affected by the immediate cause, whatever it might be, of influenza; that applied to anything which tended to debilitate the animal. Of pre-disposing causes, exposure to cold was said to be one. He disagreed that that was one of the pre-disposing causes, although he agreed generally with the others. He did not think that an animal which was in good health otherwise and fit, would be more liable to the disease from exposure to the cold.

The second question is: "What is the relationship between so-called influenza and contagious pneumonia?" Mr. Male had given the opinion of Mr. Watkins-Pitchford on that subject, and he practically came to the conclusion that there was no such thing as contagious pneumonia—in fact, that it was an idiopathic condition, and that it was preceded in the majority of cases by catarrh which was not infectious. If that was so he (the speaker) could not see that there was any connection between influenza and contagious pneumonia. Whether the condition which was said to accompany influenza or to succeed influenza was due to the same cause, of course he could not say. As he had seen it, he thought pneumonia was not a very constant complication of influenza. He had said that before at a meeting of the Society, and others did not seem to agree with him. But he had thought that there might be reasons for it. Many people included under the term "influenza" almost any catarrhal inflammation of the tracheal mucous membrane, such as the so-called "horse dealer's fever," which he was glad to see Mr. Male thought was due to the streptococcus

of strangles, because that was a view he (the speaker) had expressed before the Society about two years ago: ordinary coryza, ordinary laryngitis and pharyngitis is called influenza. In fact he saw a report not very long ago in which a catarrhal condition was called "an influenza cold," which was really, he thought, due to ordinary catarrhal fever, or to strangles infection. That sort of thing occurred frequently in horses, and with that condition one did get pneumonia and pleurisy; but he had very seldom seen pneumonia follow influenza. He had often wondered why that was so, as it seemed contrary to the experience of others. For one thing, the horses with which he was concerned were under veterinary supervision. Immediately a suspicious case was observed, instructions were issued that all horses which appeared off colour from any cause were inspected before they were sent out to work. Other reasons for infrequency of pneumonia were probably that the cases were treated very early; the horses with which he was concerned were, generally speaking, in hard, fit condition. He had Col. Watkins-Pitchford's report before him, in which it was said: "Recent observations now suggest . . . of the disease as one of an idiopathic nature rather than a specific nature, or perhaps standing mid-way between the two categories." What was meant by that he, (the speaker) really did not know,—"being due to the agency of an organism being present in but not pathogenic to the normal horse" (reading to the words) "which habits it." Then further on in the summary he says: "The great majority of cases of specific pneumonia are preceded by an inflammation of the nasal membrane, constituting the condition known as catarrh" (reading to the words) "horse to horse."

He found it practically impossible to infect horses suffering from so-called contagious pneumonia by cohabitation. Horses were put together and were fed out of nosebags which other horses with discharge had had on, and did not become infected. He (the speaker) thought that if those findings were accepted—and they were quoted by Mr. Male—he did not see how there could be any connection; he thought it was due to the debility caused by influenza, and probably accelerated by working the animal when it is not fit, or to not putting the horses under proper hygienic conditions, and thus weaken the natural defences of the animal.

"Is the pneumonia a secondary infection or a primary disease?" He had given his opinion on that.

The fourth question, "What conditions predispose towards it?" he had also dealt with. The seasons of the year probably had something to do with it; the majority of cases occurred in the spring and the fall of the year—both seasons when the horse's vitality was low.

Fifth, as to the period of incubation, he had a good many records of influenza, and he had intended to tabulate some temperature charts and other records, but time had not permitted. He had found on looking into his records that an increase in the number of cases occurred every six or eight days, but whether that was any guide he did not know. The first cases in an outbreak were generally mild, and if taken early the horses would soon be back at work. He had also noticed that horses had gone off their feed about a week before an outbreak occurred. He thought it was well known that the first cases of influenza were generally mild; towards the middle of the outbreak the cases were considerably worse, and then dwindled down in intensity, and similarly with the number of cases.

"How is the disease contracted?" He had not much to say on that question. He had under one roof from 400 to 600 horses, and that was the stable where more of the trouble occurred. He could not say that the stable was very hygienic; it was under railway arches, and very difficult to ventilate properly. There were in all about 26 arches, each arch holding about 24 horses.

The horses stood between bales; it was very rarely that a horse standing on either side of the horse which had had influenza came in with influenza. The cases occurred here and there throughout the stable; he did not think that immediate contact was necessary for the disease to be contracted. He thought that aerial contamination was the method by which the disease was carried.

On the seventh question, "How long can an animal be infective?" he could offer no opinion. Mr. Male had said that some animals act as carriers, owing to diseased foci being left in the lungs. That, he supposed, was presuming that the lung symptoms were due to the same cause as influenza, which he (the speaker) thought was very doubtful. He rather regarded influenza as a sort of toxemia.

With regard to the methods of treatment, he thought the most successful methods were practically those given by a medical man before the British Medical Association—"Go to bed and stay there." He immediately put his cases into a large box, leaving the top door open. He did not use drugs much; he often gave four to six ounces of Epsom salts, which might be repeated for two or three days. Any complications which occurred were treated as they cropped up. One got rheumatoid complications; metastatic lameness and muscular tenderness; arthritic symptoms sometimes occurred; also nervous symptoms, due probably to an infection or affection of the meninges, which respond more or less to time and treatment with Pot. iod. and Nuc. vom. As a rule when one put the horses in a loose box they would lie down, sometimes for hours together. They are off their feed, and gradually return to it in two days or so; he questioned whether it was wise to get them to feed too early. In many cases there was a catarrh of the mucous membrane of the bowel, probably of the duodenum, and of the bile-duct; he thought some of the colouring of membrane was due to the absorption of bile, due to the blocking of the bile-duct or through the swelling of the duodenum. He did not use many drugs. In his time he had probably used all the drugs in the pharmacopeia; but he found his present methods cheaper and better. Strychnine he used if heart symptoms occurred; if a horse does not come on to his feed a little carbonate of ammonia usually brings him on; if he did not do as well as he ought afterwards, a little iron or gentian might help. Each case had to be dealt with on its merits; he did not think any hard-and-fast rule could be set.

Question 9 was: "Is there any known method of inoculation which could be recommended as preventive or curative?" He had very little experience of preventive inoculation, but he did not think much benefit was derived from that. A colleague inoculated a lot of horses, and his results were set out in the following letter: "I tried a certain influenza vaccine prophylactic at Bristol during a bad attack. I took one stable and did every horse, but the result was not satisfactory. Most of the stable contracted the disease. We had 80 cases out of a stud of 115. This is my only experience of vaccine for influenza."

In reply to the tenth question—"Is there any evidence pointing to contagion or infection from animals to man, or *vice versa*?" he remarked that although there had been a lot of influenza among human beings for some months, until a few weeks ago there had been practically no influenza among horses. He had noticed, however, that when there had been influenza among the horses there were no more stablemen away ill than usual; and during the epidemic among human beings, although a good many men were away, there was no influenza among the horses. He would not say that the two had not occurred together; but certainly there was no marked connection between the outbreak among the horses and increased illness among the men.

Mr. W. PERRYMAN said the feature of the paper that had struck him was that Mr. Male seemed to be dealing a good deal more with pneumonia than with influenza. He was in agreement with Mr. Thompson rather than Mr. Male. He thought that as seen in London, influenza or "pink-eye" was a very distinctive disease from pleuro-pneumonia, and that if one got pleuro-pneumonia it was quite a secondary complication; and while he was not by any means a bacteriologist, he would say the organisms were quite different in the two diseases. As Mr. Thompson had stated, if influenza cases were placed under good hygienic conditions, one seldom got complications of pneumonia; for that reason he thought the two complaints were distinct. One did get pneumonia, he thought more of the bronchial character than the croupous pneumonia or consolidated form. He also agreed with Mr. Thompson that one fact tending to prove that influenza was not so contagious from one animal to another by direct contact, is that one frequently found one animal in one corner of a stable affected, and another on the other side. If it was entirely of a pneumonic character he would expect the next horses to get it. If one got contagious pneumonia, which generally seemed to him to be pleuro-pneumonia, one got several cases following rapidly in the same stud, and one got them at a time when one had not seen any cases of so-called pink-eye. For that reason he would certainly look upon them as two very different diseases. Many of the symptoms were different. In cases of pleuro-pneumonia one frequently found advanced consolidation of the lung itself before noticing anything very wrong with the horse; whereas in "pink-eye" or influenza there was a very severe train of symptoms, such as high fever and the swelling of the eye-lids, limbs, etc. In pleuro-pneumonia those distressing symptoms seldom occurred. There might be slightly increased breathing; but when one auscultated the chest it would be found that the disease had progressed very rapidly.

He thought there was general agreement as to the predisposing causes: bad hygienic conditions, overwork, debility. The incubation period, he thought might be better demonstrated in a general practice than in Mr. Thompson's case. Where one went into a stud and saw a case of "pink-eye," and that was the first case, on watching carefully one would undoubtedly find that in about a week the second or more cases occurred. He generally reckoned about eight days as the period of incubation.

With regard to how the disease influenza was contracted, he regarded inhalation as the chief cause, for the reason that cases occurred scattered about different parts of a stable.

He agreed with Mr. Thompson that in treatment, fresh air was perhaps the most important thing; also warmth, clothing, and if any drugs were used they should be stimulants, with a laxative. He had used stimulants, such as digitalis, nux vomica, etc., in the later stages, especially where the horse showed signs of depression through being worked while the disease was in progress. The giving of iodine was mentioned in the paper. He thought iodine was a splendid drug, but he did not agree with the large amount of iodine mentioned in the paper, because that given internally would set up a good deal of irritation in the bowels. He personally never gave more than about 10 grains in a bolus. He thought larger doses would certainly set up irritability in the bowels, and would also result in iodism of the system, and salivation. He had seen that once in a case of polyuria, the animal had colic with it; and the symptoms were very distressing. He also gave heavy doses of bi-carbonate of soda with the iodine, because he thought it was sedative to the mucous membrane.

On the question of infection of the human being—he had never felt very nervous about it himself. He

thought if it were very infective to the human subject many veterinary surgeons would get it. He had not noticed that the men who attended to the horses contracted the disease.

He did not think that inoculation was of any use, and never tried it.

Mr. MCINTOSH said with regard to the cause of influenza he had nothing to say except that the contagion appeared to be extremely volatile and spreads with enormous rapidity once it gets a hold in a stud of horses.

He was in agreement with Mr. Thompson and Mr. Perryman that influenza and contagious pneumonia were separate and distinct ailments. Whilst there were certain symptoms common to both diseases there were others quite diagnostic. Influenza is characterised by its epizootic nature, rapid spread, high temperature and great depression with digestive implications. Further there is slight catarrh of the nasal chambers; the organs of respiration were seldom involved, provided the disease is detected at its onset and proper precautions are then taken.

Contagious pneumonia, on the other hand, occurs enzootically, does not spread with the same rapidity, depression is not nearly so pronounced, the organs of respiration are primarily involved and digestive implications are very rare. Influenza is a mild complaint as compared with contagious pneumonia.

He agreed as to the predisposing causes which had been mentioned, except with regard to cold. He considered that mild muggy weather was much more likely to favour an outbreak than mere cold.

As to the incubation period, it was experimentally about five days, but naturally it varied very considerably according to the resisting powers of the animal, and might extend to ten or even fourteen days.

He thought it was possible for an animal which had to all appearances recovered from influenza to be a source of infection to others for many weeks afterwards, and possibly for a month or two. Cases were recorded where sires had conveyed the disease to mares twelve months after having had the complaint.

In the treatment, he used very few medicines. Good nursing, attention to ventilation and comfort generally, careful dieting, were practically all that was needed. If the disease is not discovered at the onset, and the animal is worked during the initial stage, complications may arise. If there is great depression and cardiac debility, he generally gave injections of strychnine hydrochlor. or perhaps digitalis. In gastric affections possibly a saline, or a little calomel with enemas.

In all outbreaks of influenza he had the temperatures of his stud taken morning and night with a view to detecting the disease at its first onset.

Mr. IRVING said his experience had been that the heavy cart horses had been much more liable to the disease than the lighter breeds; the thoroughbred suffered least of all. He had seen horses out at grass, away from all infection, contract the disease. He had had cases such as Mr. McIntosh had mentioned, where the horse suffered from muscular ailments afterwards; a great many horses became shiverers after it.

Mr. DE KOCK said he felt honoured to be invited by the President of the Society to address the meeting. He had been working with Sir Arnold Theiler, at the Veterinary Research Laboratory, Pretoria, for about five years, and during that period there had been several outbreaks of what has been styled "Infectious Catarrhal Fever of Horses." It was of a very infectious nature and spread through the country with great rapidity, affecting most of the animals. They did not feel reconciled to call it "pink-eye" for the reason that the disease started with catarrhal symptoms, and lacked that marked depression which was one of the characteristics in equine influenza, and also the peculiar colouration of

the conjunctival mucous membrane to which the disease owes its popular name.

This infectious catarrh was generally recognised in the morning by examining the charts of the horses in the various experiments, when a rapid rise of temperature was evidenced, sometimes going up to 105 and even 106. It remained irregularly remittent for quite a number of days and then dropped down to normal. Sometimes a relapse may be observed, somewhat resembling the initial stages of a subacute form of "Equine Infectious Anaemia." With the rise of temperature catarrhal symptoms become evident, beginning as a slight serous discharge from the nostrils which with the progress of the disease becomes more purulent in character. Further there does not seem to be much impairment. Occasionally slight fever was shown with only slight serous discharge from the nostrils.

The disease was of a fairly mild nature in South Africa. They never had a case of post-mortem. There had only been as far as he can remember two cases of deaths, these being complications in the form of Purpura Hemorrhagica. The nature of the disease was not investigated on account of insufficient staff.

In speaking of Infectious Pneumonia, he would like to mention an experience of Sir Arnold himself, which happened before the Anglo-Boer War at the State Artillery Barracks. A specific infectious pneumonia of a severe character affected a great number of the horses, and with a fairly high mortality. At post mortem a croupous pneumonia was evidenced. There was no sign of equine influenza at that time. On the other hand it must be remembered that pneumonia often occurs as a sequel in many of the other debilitating diseases, such as Nuttalliosis, equine infectious anaemia, etc., and on post mortem one meets with a broncho-pneumonia which sometimes becomes gangrenous. He did not know "pink eye" himself, but he took it from Sir Arnold that it differed from what they called the infectious catarrhal pneumonia. In the latter case the respiratory tract was mainly affected. It might be a form of strangles and in a few cases a streptococcus had been observed. Of course the etiology of influenza and all the different pneumonias had not been properly investigated and needs further research work.

Lieut. MARTEN, U.S.A., Veterinary Corps, said he had not read the paper; he had glanced over it; but he had listened to the discussion with great interest. They had what they called influenza in the States, and the symptoms were as outlined. They had found that most of the influenza broke out in Army camps; it did not occur so much in civilian life. He always thought the disease was due to debility caused by the animals being shipped for two, or three, or four days by railroad. He had read an opinion that the cause of influenza was in the animal's body all the time, and that when the animal became debilitated the infection became more prominent, and the animal got influenza or catarrhal fever. He found that pneumonia often followed influenza. He thought that contagious pneumonia and influenza were quite different diseases. He agreed that heavy draught horses were more subject to the disease than lighter breeds. He did not give much medicine; hygienic conditions, and plenty of fresh air and fresh drinking water formed the treatment. Occasionally he gave nuxvomica or gentian to build up the appetite, and if the animals were very weak strychnine might be given. He had used a good many serums, but had not found them very effective—though of course the serum companies claimed they were very good. (Laughter)

Capt. LEITCH, Australian Veterinary Corps, said he felt some embarrassment in addressing a meeting of that kind on such a subject, but he might give an account of one or two experiences he had met with. About five or six years before the war there had been a bad outbreak

of the disease in Melbourne and the provincial towns of Victoria. About 80 per cent of all the horses in those towns were affected, and the commerce of those cities was tied up for a week or ten days. The treatment had been simply stimulants and tonics where necessary, the main part of the treatment was to take the horse off work as early as possible; if they went on working they nearly all died, but if they were taken off work, not one died. Veterinary surgeons was rather few and far between out there, but that was the opinion of all of them. With regard to the catarrh mentioned by Mr. de Kock, he had seen that in Africa. During the war, in Cairo he had a large remount depot; he was there 16 months, and there was a very bad outbreak. The practice was to put all the affected animals into one kraal, and the thing died out in ten days' time. That was the only thing to do when one had to deal with 700 or 800 horses; there was very little white labour, though there was plenty of black. He did not know whether the pneumonia which occurred on board ship came within the scope of the discussion, but he had experience of the disease on three voyages. In his opinion it was an entirely different disease from influenza. In one outbreak, out of 780 horses on the way to Africa, only one died; in another instance only two were lost out of 600; in another instance one was lost out of three or four hundred. As soon as he found the temperature going up he had cold water thrown over the animals, kept going all the time, so as to reduce the temperature as quickly as possible, and generally he found that in a day or two they were on their feet again. That was all he ever did, and he thought that was why he got good results.

Mr. F. G. SAMSON said he agreed with practically all the symptoms as described by Mr. Male. He thought that bad cases of influenza were due wholly and solely to keeping the horse working too long. He thought the more serious attacks occurred in the towns, rather than in the country. He remembered a case of a racehorse, the property of the late Mr. Edward Wragg. All he did in that case, as far as treatment was concerned, was to turn the horse into a paddock and leave him there a few hours twice daily when warm and fine. He believed he did have one good dose of mustard on his chest and sides. It was a good plan to pay regard to the bowels. Epsom salts had been mentioned. He much preferred Glauber's salts to Epsom salts; he found that Glauber's salts was much less depressing, and did not remain about the system so long. He believed a good mustard plaster to the sides of a horse was a very good thing; if circulation was bad and the breathing accelerated. He knew some eminent men said it was irritating; so it might be, but he knew it warmed them up and set the circulation going. He believed in carbonate of ammonia in cases where the animals got low; a drachm, or two drachms with gentian twice a day, or three times if necessary. Another very good thing to do was to lead the horse out two or three times a day, even if it was only for a few yards or so; it assisted the circulation, and prevented the infiltration into the legs. He thought pneumonia was quite a different disease from influenza. He had had nothing to do with vaccines at all.

Major P. J. SIMPSON said he thought influenza and contagious pneumonia were entirely separate diseases. He remembered one unfortunate outbreak of pneumonia when he took a shipload of horses out to Egypt in 1915.—It was not such a happy voyage as Capt. Leitch had described.—Curiously enough, the boat was a new one; it had never had a horse in it before. The horses were all healthy when the trip started; but the first death occurred within three days of leaving England, and that was only the first of several. That was undoubtedly contagious pneumonia. He also remembered when the yeomanry were mobilised at Reading for the South African War, their departure was delayed by an

outbreak of influenza in the stables there and although pneumonia occurred as a complication the cases presented very different symptoms to the outbreak on board ship. He found that when animals were kept in the open the disease did not occur; he had practically none during the present war. He had experience in Egypt of the catarrh referred to by Capt. Leitch, and the method of treatment was the same as had been referred to; the affected animals were put into a separate kraal. The horses all came out perfectly well, and not a grain of drug was given to them. He did not think that cold was a pre-disposing cause of influenza; ill-ventilation of stables was a much more potent cause.

The PRESIDENT in closing the discussion said he thought Mr. Male in his excellent paper had purposely put up some opinions to be hit at. The point which interested him most was the question of the identity or otherwise of influenza and contagious pneumonia in the horse. He held very strongly that the two diseases were quite separate and distinct. His opinion was based mainly on the difference between the symptoms. In his experience, in influenza in the horse, intense depression was the most predominant feature, accompanied by loss of appetite, followed in a day or two by elevation of temperature. In the case of contagious pneumonia it was just the reverse. The horse did not go off its feed until he had a high temperature, very often for 24 hours, or even 48, or sometimes three days; often the disease was not noticed for some time. In the case of influenza it was impossible not to notice that the horse was ill. Again, the character of the pulse and the circulation differed considerably. In influenza there was a soft, slow, sluggish, drawn-out pulse; whereas in contagious pneumonia there was a pulse of good tone, more of the characteristic febrile pulse that is described as "full and bounding." In influenza there often occurred complications such as catarrh of the alimentary tract, and edema of the limbs; and he had not come across either of those complications in contagious pneumonia. Another complication met with in influenza but not in contagious pneumonia, is jaundice. With regard to the quotation from Hutyra, he considered that the fact that no one had yet artificially produced pneumonia was no argument that it did not exist as a separate disease; it was simply begging the question. He thought most members would agree that pneumonia might occur secondarily as a complication of influenza, but when it did occur it was not etiologically the same disease as that generally regarded as contagious pneumonia of the horse. When pneumonia occurred as a sequel to influenza, it was brought about by a variety of organisms; it was sometimes due to the streptococcus, and sometimes to the ovoid bacillus.

The cause of the croupous pneumonia which occurred sometimes primarily was not yet determined, but the organism usually present in greatest numbers was the ovoid bacillus described by Lignières. On the Continent the principal view held was that what we call contagious pneumonia is simply a pectoral form of influenza, but that view was not widely accepted in this country, especially amongst practitioners with wide clinical experience of both conditions.

As to the transmissibility or otherwise of the disease from animals to man, he had not yet found any evidence that the disease was so transmitted, and in his view there was no association between the two influenzas.

Questions have been asked with regard to the muscular and nervous complications sometimes met with in influenza. He had seen them frequently, and in thoroughbreds especially it was not uncommon to get a rolling gait and a weakness of the loins that almost suggested kidney or spinal complications. He attributed that to general debility rather than to spinal affection. It was similar to staggering in dogs with great debility in uncomplicated but severe distemper.

In the treatment, in cases either of influenza or contagious pneumonia where there was a commencing very high temperature, it was a good plan to use some antipyretic to reduce the temperature as quickly as possible; he employed salicylate of soda or acetosalicylic acid, in 2-drachm doses, applied to the tongue with treacle, and repeated perhaps twice or three times in the course of two days. When that was discontinued, either simple salines, or if there was much debility hypodermic injections of strychnine or digitalin would be found useful. His experience of vaccines corresponded with that of other members who had spoken—he had not found any benefit from their use.

#### REPLY.

Mr. MALE said that the object of the paper, as the President had remarked, was to promote discussion, and if possible to arrive at some definite conclusion on the points he had brought forward. There were some things upon which every one was agreed—which was something. They were agreed about fresh air; about the giving of Epsom salts to the horse as a laxative; most members were agreed as to the use of stimulants and not depressants; although Prof. Wooldridge had mentioned acetosalicylates, which he (the speaker) rather regarded as too depressing in influenza, in view of the heart's action being already so depressed. He had expected to get a wiggling for discarding quinine so abruptly. Quinine seemed to have been a sheet-anchor for many years, and so he had taken the trouble last night of looking up the authorities on the action of quinine, and he had found that it was a great depressant in every way. It depressed respiration, and if given in large doses it paralysed it altogether; it depressed the action of the heart, and it decreased the action of the white blood corpuscles; but as no one had advanced the giving of quinine his labour of love in looking up the authorities had proved to be unnecessary. Most members were also agreed that the vaccines were of little use. They were all agreed that the temperatures should be taken frequently, and that any horse with a high temperature should be stopped from work—that if a horse was worked he would get pneumonia.

But members were not agreed at all as to whether pneumonia was a complication of influenza, or whether it was a separate disease. He was really very disappointed at the arguments put up against the theory which he had tried to propound in his paper. Nearly every speaker had agreed that they were entirely different diseases, but there were only two speakers who gave any reason for that view. The others were men who had a great experience of horses, and whose opinions he valued very highly; and they admitted that their stables were hygienic, that they took the horse's temperature, that in fact they did not give the horses a chance to get the pneumonia, and they all made the remark that they thought it was a secondary complication. Well, that was what he had contended all the way through; that it was the influenza organism that weakened the defences of the body, and that the horse, if he was put under certain adverse conditions, was rendered liable to the attacks of the pneumonia organism, which in some outbreaks took on an increased virulence, whereupon the pneumonia rapidly developed—masked the symptoms of influenza in some cases. That was what occurred in the outbreak he had quoted. The typical symptoms of influenza, and what were laid down as the typical symptoms of contagious pneumonia, all occurred in the same outbreak.

The PRESIDENT said that with Mr. Male's permission he would like to add one point which had slipped his mind, tending to show that contagious pneumonia might occur absolutely independently of influenza. If it was always a secondary infection following on influenza, there must always be first the preliminary attack of in-

fluenza, which must last several days, after which the pneumonia would develop; but in numerous cases in his personal experience there had been no such preliminary stage.

Mr. MALE said he would take Prof. Wooldridge's points seriatim. His first point was that in cases of influenza the horse was off his feed, and that was the first symptom; whereas in contagious pneumonia the horse fed well. All the other members who had spoken had borne him (the speaker) out that, as in contagious pneumonia, a rising temperature was the first symptom of influenza and for that reason had advised frequent taking of temperatures. In so-called cases of contagious pneumonia that he had dealt with, one of the first signs noticed was that the horse was off his feed, as in the case of influenza (but in both diseases a rise in temperature was to be looked for).

Then the President made a strong point with regard to the pulse, which he had made also in a paper before another Society. The authorities generally agreed with his (the speaker's) observations, that the pulse in influenza was a hard, quick pulse, such as Prof. Wooldridge had described in pneumonia. (Who could imagine a horse with a temperature of 106° with a slow, full pulse). He thought that disposed of that point. (Laughter) Then with regard to catarrh, the President had said that catarrh occurred in influenza; he was not clear whether he meant nasal catarrh as well as abdominal catarrh and swelling of the limbs; whereas neither of those symptoms occurred in contagious pneumonia. Now it was established that in influenza catarrh affected most of the organs, the respiratory tract and the abdominal tract, and there was a discharge from the nose in many cases. In Law's table of diagnostic symptoms of the two diseases he said that in contagious pneumonia there was discharge from the nose, and that in both cases it was yellow, and his own observations confirmed this.

The PRESIDENT said that he did not refer to nasal catarrh at all; it was intestinal catarrh which was absent in pneumonia.

Mr. MALE replied that the catarrh affecting the bowels in contagious pneumonia was even more marked than in influenza; a horse often got severe diarrhoea also, and when those symptoms occurred the horse would probably die.

The PRESIDENT said that was so in a moribund horse, but not in a horse in a typical condition.

Mr. MALE said that the catarrh of the bowel was typical of contagious pneumonia, even if diarrhoea did not occur. Catarrh of the bile-duct also occurred, as was proved by the bilious condition of the membranes. The post-mortem lesions in a horse which had died of influenza complicated with pneumonia were identical with those where a horse died of so-called contagious pneumonia. Freidberger and Fröhner, Laws, Hutyra and Marec, all agreed on that point. With regard to swellings, in the case of the outbreak he had quoted (which the President thought was contagious pneumonia) many of the horses got swelling of the limbs; so that if Prof. Wooldridge contended that that was an outbreak of contagious pneumonia, then he would have to admit that the swellings in the limbs were symptomatic of contagious pneumonia. Some authorities described contagious pneumonia under a special head, and under that special head they described the symptoms of swelling of the legs—in fact there was another synonym given for that. The points which Prof. Wooldridge had pointed out as diagnostic symptoms disagreed with his (the speaker's) observations, they disagreed with some of the other speakers' observations, and they disagreed with most of the authorities he had consulted; so that as far as he could see no points had been brought forward which held water to refute the suggestions he had made! (Laughter.)

With regard to the transmission of the infection from horses to man, he was rather interested in the recent outbreak in human beings; and having had influenza, and watched other people have it, it struck him very forcibly that the disease was practically identical with that occurring in the horse. Most medical men agreed that pneumonia was a secondary complication to influenza, as he thought was the case with the horse. There was considerable doubt as to the cause of influenza in the human subject. Pfeiffer had found and described a bacillus, but it was very doubtful at present as to whether that really caused the disease; medical men inclined to the view that the cause of the disease was an ultra-microscopic organism. He had a letter from a past-President of the College—he would not mention his name—which said: "I personally thoroughly endorse all you have written." A Professor known to the members had told him that he had observed what he thought were cases of infection from horses to man. So that there was some evidence to support his suggestion. Of course, as in many other diseases, the conditions must be suitable for infection. In the outbreak of influenza among human beings the increased virulence, he had no doubt, was due to increased herding of people owing to the war. In the same way with horses, there would be the increased virulence of the organism which caused the lung symptoms, with also possibly the influenza virus; and if the men were put under those adverse conditions then he thought there might be a chance of their becoming infected from the horse; but he hoped experiments would be made to prove or disprove that. He noticed that most of the authorities in the text-books said there was absolutely no connection; that Pfeiffer found a bacillus, and therefore there was no connection between the two. That was the chief argument they advanced as to there being no infection from horse to man—because Pfeiffer found a bacillus; but Pfeiffer's bacillus had got rather into bad repute recently, so that possibly the text-book would be revised in its next edition.

A vote of thanks to Mr. Male for his paper was carried with acclamation.

#### LETTER FROM MR. LESLIE SCOTT, K.C., M.P.

The PRESIDENT inquired whether members desired that Mr. Leslie Scott's letter should be returned to him for amplification of the points he had raised, or whether they would like to appoint a small committee to go into the matter and bring recommendations forward.

Mr. WILLETT said he thought a small committee might be formed to go into the matter after Mr. Leslie Scott had been heard from again, and bring its conclusions before the next meeting.

Mr. McINTOSH thought that Mr. Leslie Scott could give no further information; the points were quite clear. They knew what he meant.

The PRESIDENT thought it was not quite clear what he did mean.

Mr. IRVING said it was by no means clear; it was altogether too indefinite. He proposed that Mr. Leslie Scott should be written to, and asked to elaborate his questions, and give a definite statement as to what he proposed to do before the Society discussed the matter. Mr. Willett formally seconded, and this course was agreed to.

HUGH A. MACCORMACK, Hon. Sec.

#### NORTH OF IRELAND V.M.A.

The following resolution was passed by the Council of the North of Ireland Veterinary Medical Association at their meeting held in Belfast on the 12th May 1919:—

"That having carefully considered the proposed Bill of the National Master Farriers Association, we are de-

terminated to oppose it by every means in our power, as it threatens to interfere with the rights of veterinary surgeons to conduct the business of horseshoeing. And we beg to suggest to the Council of the Royal College of Veterinary Surgeons, that a committee be formed to look after the interests of our profession in the passage of the Bill."

"That they also wish to express themselves in entire sympathy with the Anæsthetics Bill at present before Parliament, and trust that its passage may be secured."

May Street, J. EWING JOHNSTON, M.B.E., M.R.C.V.S.  
Belfast, 15th May. President

### THE DIGNITY OF THE PROFESSION.

To the Editor of "The Veterinary Record."

The following advertisement for a Veterinary Inspector in lieu of the late Mr. E. Manwell, M.R.C.V.S., deserves publication.

It shows in what light the Local Authority sanctioned by the Veterinary branch of the Irish Department of Agriculture views the administration of the Diseases of Animals Act.

Is it any wonder that notifiable diseases are prevalent even more so than the weekly returns lead one to suppose.—Yours faithfully,

Kells, Co. Meath, J. FOX, M.R.C.V.S.

#### MEATH COUNTY COUNCIL: APPOINTMENT OF VETERINARY INSPECTOR.

"The Meath County Council will at their Quarterly Meeting to be held on Monday, 26th May, 1919, at eleven o'clock in the forenoon, at the County Hall, Navan, consider applications and appoint a Veterinary Inspector under the Diseases of Animals Acts for the Ardee No. 2 Rural District of County Meath.

The person appointed will receive a salary of £15 per annum, same to be in full discharge of all duties to be performed by him under the Diseases of Animals Acts or Orders in Council thereunder now in force, or which may hereafter be enacted; or under any direction of the Department of Agriculture and Technical Instruction, or the Local Authority or its Executive Committee under the said Acts, and to include mileage or attendance at such Fairs and Markets as may be required.

It will be necessary that the person appointed reside within the area comprised by the Ardee Union.

Appointment to be subject to the approval of the Department of Agriculture and Technical Instruction.

Applications will be received not later than eleven o'clock in the forenoon on Monday, 26th May, 1919. Personal attendance of candidates necessary at time of election. By Order,

County Hall, JOHN J. GRENNAN, Secretary.  
Navan, 28th April, 1919.

### "CONSULTATIONS, ADVICE, ETC."

Sir,—The following inscription appears on a board attached to a little house in the main thoroughfare of a town near Reigate:—

H. P. REID,  
late R.A.V.C.

Consultations, advice &c. in special cases by expert veterinary surgeon arranged.

I am sending the above to the Royal College of Veterinary Surgeons in the hope they will communicate with the Army Veterinary Department, but in the meantime it behoves all members of the profession to watch for such sign boards as above, as quackery after the great war is bound to be rampant.—I am, Yours faithfully,

The Gables, Reigate,  
22 May 17.

CHAS. A. SQUAIR.

Dear Sir,—“Fools rush in where Angels fear to tread” and I daresay I shall draw down the wrath of the mighty unknown if you care to print this protest; but why all these pen names, Dagonet, Diogenes, etc., why should a man be ashamed of his own name? Personally I am only a poor, dense and doubtless misguided country practitioner, but I am never inclined to place much value on opinions expressed over a pseudonym and I believe there are many others of the same way of thinking.

All this froth arises because I have just been reading “Dagonet” in yours of May 3rd; now, I have had the pleasure of meeting both Mr. J. Willett and Mr. McIntosh and can place a definite value on their opinions but Mr. D, well of course he is only an unknown shadow.—Yours truly,

Lechlade, Glos.  
May 20.

J. R. BAXTER

### THE ROYAL SANITARY INSTITUTE.

Patron: His Majesty the King.

Congress at Newcastle-upon-Tyne, July 28th to August 2nd, 1919. Arranged at the invitation of the Mayor and Corporation. President of the Congress: His Grace the Duke of Northumberland.

The arrangements for the meeting will include:—President's Inaugural Address. Lecture to the Congress. Popular Lecture.

Sectional Meetings for the reading and discussion of papers relating to:—Sanitary Science and Preventive Medicine. Engineering and Architecture. Hygiene of Maternity and Child Welfare. Personal and Domestic Hygiene. Industrial Hygiene.

Conferences: Representatives of Sanitary Authorities. Representatives of Port Sanitary Authorities. Medical Officers of Health. Engineers and Surveyors. Veterinary Inspectors. Sanitary Inspectors and Health Visitors.

It is proposed to arrange in connection with the meeting a Health Exhibition specially illustrating Hygiene of Infants and Child Welfare, Housing, including laying out of estates, planning, materials and construction, fittings and appliances; Ship Sanitation, etc., as well as matters relating to Municipal Sanitation and Domestic Health and Comfort.

Visits are arranged during the Congress to Water Works, Sewage Disposal Works, Isolation and other Hospitals, and other places of Sanitary interest.

### ANIMALS (ANÆSTHETICS).

A Bill to make further provision for the Protection of Animals from Cruelty. Presented by Lieut.-Col. Walter Guinness, supported by Lieut.-Col. Archer-Shee, Sir Frederick Banbury, Mr. Bottomley, Mr. Butcher, Major Courthope, Lieut.-Col. Greene, Sir Samuel Hoare, Mr. T. P. O'Connor, Major O'Neill, Mr. John Jones and Sir Philip Magnus.

1—(1) If any person shall subject or cause or procure, or being the owner permit to be subjected an animal to an operation contrary to the regulations contained in this section, he shall be guilty of an offence under this Act.

(2)—(a) A horse shall not be subjected to any operation specified in the First Schedule to this Act, and a dog shall not be subjected to any operation specified in the Second Schedule to this Act, unless the animal during the whole of the operation is under the influence of some general anæsthetic of sufficient power to prevent the animal feeling pain.

(b) A horse two years old and over shall not be subjected to the operation of castration unless during the whole of the operation he is under the influence of some general anaesthetic of sufficient power to prevent him from feeling pain.

(c) A horse shall not be subjected to any operation specified in the Third Schedule to this Act unless during the whole of the operation it is under the influence of some general anaesthetic or some local anaesthetic being, in either case, of sufficient power to prevent it feeling pain.

2—(1) Any person who is guilty of an offence under this Act shall be liable on summary conviction in respect of the first offence to a fine not exceeding five pounds, and in respect of any second or subsequent offence to a fine not exceeding twenty-five pounds, or alternatively, or in addition thereto, to be imprisoned with or without hard labour for any term not exceeding three months.

(2) An appeal shall lie from any conviction or order by a court of summary jurisdiction under this Act to quarter sessions.

3—(1) The Board of Agriculture and Fisheries may, by order made subject to the provisions of this section, add any other operation to the operations specified in any schedule to this Act, and any operation so added shall be deemed to be an operation specified in that schedule, and the Board of Agriculture and Fisheries may also by order made as aforesaid extend any provision of this Act to any domestic animal to which it does not at the time apply, with such modifications or additions as may appear to that Board to be necessary.

(2) The draft of any such order shall be published for a period of two months before the order is made, and the Board of Agriculture and Fisheries during that period shall receive and consider any representations made to them with respect to the order by any persons appearing to them to be interested in the subject of the order.

(3) The order, when made, shall forthwith be laid before Parliament, and shall not take effect until it has so lain for thirty days before each House of Parliament, being days upon which that House has sat, and if a resolution is passed by either House before the expiration of such days declaring that the order be annulled, the order shall not take effect, but if no such resolution is passed the order shall take effect on such day after the expiration of the last day on which any such resolution might have been passed as the Board of Agriculture and Fisheries may appoint.

4 In this Act, except the context otherwise requires the expression "dog" includes and bitch, sapling, or puppy; "general anaesthetic" shall include chloral hydrate, and in the case of a dog morphine.

#### SCHEDULES.

*First Schedule.* Radical operation for quittor. Line fring. Operation for stripping the wall of the hoof or sole. Radical operation for poll evil. Radical operation for fistulous withers. Ovariectomy. Laparotomy.

*Second Schedule.* Castration. Ovariectomy. Laparotomy.

*Third Schedule.* Neurectomy or unnering. Enucleation of the eyeball. Trephining.

#### MEMORANDUM.

The Cruelty to Animals Act, 1876, provided for the use of anaesthetics in the case of all experiments calculated to cause pain. There is, however, no restriction of any kind on operations performed in the ordinary course apart from research.

This Bill would make it an offence to perform certain scheduled operations on horses and dogs without the

use of an anaesthetic. It would not interfere with the present practice of castrating colts, but would make an anaesthetic compulsory when this operation is performed on horses two years old and upwards.

The schedules deal only with operations on horses and dogs, but the Bill would empower the Board of Agriculture to order the use of anaesthetics for such other operations on domestic animals as might be thought advisable after full enquiry, and after laying a draft order for thirty days before each House of Parliament.

In the House of Commons, May 2.

Lt.-Col. WALTER GUINNESS, in moving the second reading, said:—

"The advance of medical science has not brought any alleviation of suffering to animals in the way that it has to human beings. It has, indeed, too often greatly increased their sufferings, because there are now performed on animals surgical operations which were never dreamed of in the days before the discovery of anaesthetics revolutionised surgery. There are, no doubt, many humane owners who make a point of demanding the use of anaesthetics for their animals, but in the enormous majority of cases horses and dogs do not have the benefit of anaesthetics in the complicated and severe operations in which they would invariably be used as a matter of course in the case of human beings. This Bill has never been discussed in the House of Commons, but it has been very considerably discussed in the country, and has been modified to meet the views of agriculturists and of the veterinary profession. I first drafted a Bill on this subject in 1912, as the result of myself seeing a great many veterinary operations at the Royal College of Veterinary Surgeons and elsewhere. In its original form the Bill, besides making anaesthetics compulsory in the case of certain scheduled operations, forbade the castration of pigs and bulls over the age of six months except in the case of disease. This was strongly opposed by agriculturists, and to meet their views I reintroduced the Bill in 1913 without the provision as to pigs and bulls, and, in the case of horses, limiting the compulsory use of anaesthetics to the gelding of two-year-olds and upwards, where, owing to the larger size of the blood vessels, the operation is more protracted and painful than in the case of colts. In 1913 the Cattle Diseases Committee of the Central Chamber of Agriculture wrote approving of the Bill in its amended form. Clause 3 would enable the Board of Agriculture to extend the Schedules and to apply them to other domestic animals, after fulfilling certain necessary provisions to secure that agricultural interests are not forgotten. Ill-luck in the ballot prevented any progress with the Bill in 1913, and in 1914 further changes were made in the scheduled operations to meet criticisms which had been developed by a very considerable correspondence in the columns of the 'Veterinary Record,' the 'Veterinary News,' the 'Veterinary Journal,' and elsewhere. The proposal in its present form has been very carefully discussed, and it is the result of an agreement to meet those agricultural and veterinary interests which had the best claim to be considered. The scheduled operations are limited to those on horses and dogs, and a distinction is drawn between operations which should be performed under a general anaesthetic and those for which only a local anaesthetic is required. I know it may seem rather curious to lay down anything stringent in the way of distinction between local and general anaesthetics, but I am told by young and progressive members of the veterinary profession that there is so much prejudice among certain of the older men against the use of anaesthetics that, unless it is definitely laid down what shall be used, many operators will go on with the present practice of using no effective anaesthetic whatever."

"I ought perhaps to say that this Bill was in no way suggested by the veterinary profession. Obviously, it would be a very invidious matter for them to bring forward. But although it is brought forward by myself and owners of animals who had seen veterinary operations themselves, we have certainly had the help of veterinary surgeons, who have been good enough to give very valuable criticism and advice. From the first the drafting of this Bill has met with strong support among horse-owners. It is going, I hope, to be seconded to-day by an hon. Member who takes a great interest in racing, and I am quite certain that, unless the measure was considered imperative in the interests of humanity, we should not have had the support which has been forthcoming in the past. More than one veterinary surgeon has confessed to me his feelings of horror at the sufferings he has had to inflict owing to the refusal of owners to allow the use of anaesthetics. In view of the fact that it has long been recognised that, if a horse is unfit for work, no financial consideration shall absolve its owner from liability to a charge of cruelty if he does work it, it is surely not too much to provide that where owners for their own convenience and profit subject their helpless animals to severe and painful surgical operations, they should be compelled to find the few shillings which are necessary to secure the use of an anaesthetic.

The following are portions of the debate :—

**Sir WILLIAM WHITLA :** I just want to say that I do not believe that you would get one dissentient voice among the 25,000 medical men. I believe that they would all accept this Bill with satisfaction and with very great pleasure. I want to associate myself with all that has fallen from the hon. and gallant Member who introduced the Bill. I think he may be perfectly satisfied that docking can be adequately dealt with by the use of local anaesthetics, and if on the Committee stage of the Bill docking is included among the operations to be dealt with in that manner, I think that is all that is required. The Bill should also be applied to dogs. I cannot see why colts under two years should be exempted.

**Lieut.-Col. GUINNESS :** The reason is that you cannot perform the operations now almost universally applied to colts under a general anaesthetic. There was a tremendous amount of opposition to the Bill in its original form because it applied to colts.

**Lieut.-Col. RAW :** I agree with my colleagues that a very large number of operations can be performed efficiently with local anaesthetics instead of with general anaesthetics; there is no doubt about that. I should like to ask the hon. and gallant Gentleman if he is quite satisfied that it would be possible to give general anaesthetics to animals in all the cases mentioned in the Bill. The progress of veterinary science and veterinary surgery has been extraordinarily great during the last few years. We all know the difficulty of giving animals, and especially horses, general anaesthetics, and it might be that the extension of the list of operations under local anaesthesia might be less harmful to some animals than an attempt to give general anaesthetics.

**Sir H. GREENWOOD :** May I say at once, on behalf of the Home Office and of the Board of Agriculture, that we do not oppose the Second Reading of this Bill? The measure itself is backed by Members sitting in all quarters of the House, and those who have spoken in support of it have done so with a special knowledge of the animals to which it refers. I want the hon. and gallant Member for Bury St. Edmunds and the hon. Gentlemen who support him to allow the Board of Agriculture or the Home Office when the Bill gets into Committee to make certain Amendments not with the object of affecting the principle of the Bill, but with the

object, in the first place, of bringing the penalty and appeal Clauses into line with the Summary Jurisdiction Act, I must also qualify my acceptance of the Bill by retaining the right to introduce at the proper time words or a new Clause to this effect :—

"But nothing in the Act shall apply to any experiment to which the Cruelty to Animals Act, 1876, applies."

There may be other Amendments in Committee put forward by the Departments for which I speak to-day to more clearly define or qualify certain words and phrases and to make the Bill more accurately secure, an object which I think is most laudable.

Bill read a second time, and committed to a Standing Committee.

#### TUBERCULOUS CATTLE.

Brigadier-General Sir Owen Thomas asked the Parliamentary Secretary of the Board of Agriculture whether, in view of the increase in tuberculous cattle in this country and the consequent danger to young children due to the consumption of infected milk, he would put in force the Order for compulsory notification by the owners of such cattle, which was suspended in 1914, and secure to the owners a fair compensation for cattle compulsorily slaughtered.

**Sir Arthur Boscawen :** The Tuberculosis Order of 1914 was issued under powers given to the Board by the Diseases of Animals Act, 1894, with the view of preventing the spread of tuberculosis in cattle. It has been decided to re-issue the Order as soon as the Milk and Dairies Act comes into operation. The Order provides for compensation according to scale for cattle slaughtered under its provisions.

#### Demobilisation R.A.V.C.

The War Office announces that the demobilisation of units of the Royal Army Veterinary Corps and Royal Army Ordnance Corps is still attended with some difficulty, especially in Egypt. Demobilisation of other units entails increased efforts on the part of the R.A.V.C., whose duties now comprise the taking over of incapacitated animals, classifying them according to age and soundness for ultimate disposal, and preventing disease among them.

Similar considerations apply to the demobilisation of the R.A.O.C. The Corps has to take over all the discarded impedimenta of dispersed units which require adequate custody until finally disposed of.

#### Prosecution by R.O.V.S.

At the Elham Petty Sessions on Thursday, before Mr. J. E. Quested (in the chair) and other magistrates, E. H. S. Champneys, of Sellindge, was summoned for unlawfully acting as a qualified veterinary surgeon. Mr. A. K. Mowll appeared for the Royal College of Veterinary Surgeons, and Mr. H. Stainer for defendant, who pleaded guilty.

Mr. Mowll said defendant was a very able man with regard to horses and had done business in the district for some years, but he was not a qualified veterinary surgeon. In this case Mr. Clement Hobson, of the Elham Stud Farm, wished to send some horses to Ireland, and it was necessary for a certificate to be filled in, certifying the animals were all right. Mr. Champneys was called in to examine the horses, which he did, and on the certificate which it was necessary to fill in he signed himself as a qualified veterinary surgeon. The College took a serious view of the case.

Evidence was given by Nicholas Crogan, stud groom to Mr. Clement Hobson. When the defendant filled the certificate up it was getting dark. Mr. Champneys did not say he was not qualified.

For the defence Mr. Stainer said he understood from the defendant that he told Mr. Crogan he was not a qualified man and that he should call in Mr. Gulleford. When defendant signed the certificate it was getting dark. Of course he should have carefully looked at the document. There was no question of defrauding anyone.

Defendant was fined £2 and £1 1s. special costs.—*The Kentish Observer.*

### The Public School Spirit.

People who love to stir up class wars are very hot just now on decrying "the public school spirit." I think they would have had their eyes opened had they been—as I was—at a meeting in London on Friday to discuss a war memorial to fallen Old Wellingtonians. 606 killed, 750 wounded! When you are reminded by Sir Ian Hamilton that the number of wounded in past wars has generally been 4 or 5 times larger than the number of killed, these figures strike you, as they struck him, as evidence of "quite exceptional determination and valour." It was from the O.T.C.s that we got the officers, and the Duke of Connaught affirms that it was the public-schools who made the O.T.C.s.—*The People.*

### THE R.A.V.C. COMFORTS FUND.

By kind permission of the President, a meeting of the Royal Army Veterinary Corps Comforts Fund will be held at the Royal College of Veterinary Surgeons, Red Lion Square, on Tuesday, 3rd June at 3 o'clock, to decide the disposal of the balance in hand when the Fund is finally closed. All contributors are earnestly invited to attend.

E. A. BLENKINSOP, Hon. Sec.  
29/7 Bramham Gardens, S.W. 5

Original articles and reports should be written on one side of the paper only and authenticated by the names and addresses of writers, not necessarily for publication.

## ARMY VETERINARY SERVICE

### Extracts from *London Gazette*

WAR OFFICE, WHITEHALL, May 17.

The following are among the Decorations awarded by the King of Italy at various dates to the British Forces for distinguished services rendered during the campaign: The King has given unrestricted permission in all cases to wear the decorations and medals in question:—

### CROCE DI GUERRA.

\* \* \*  
Capt. (act. Maj.) T. J. FAITHFULL, (Spec. Res.)  
Temp. Capt. G. GREEN.  
Temp. Capt. M. SPARROW.  
Capt. (actg. Maj.) W. STOTHERT, O.B.E., (T.F.)

### REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

May 13.  
Temp. Capt. E. J. Burndred relinquishes the actg. rank of Maj. on vacating the appt. of D.A.D.V.S. (Apr. 23),

May 15.  
Maj. and Bt. Lt. Col. A. Olver, C.B., C.M.G., F.R.C.V.S. relinquishes the act. rank of Col. on ceasing to hold the appt. of D.D.V.S. (April 1); Temp. Capt. J. F. Donnelly resigns his commn. (May 16).  
Can. A.V.C.—Temp. Capt. J. Biron retires in the British Isles (April 30).

May 20.  
Temp. Hon. Capt. J. Brown relinquishes his commn. on ceasing to be empld. (Mar. 24), and retains the hon. rank of Capt.

### TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

May 19.  
Temp. Capt. (actg. Maj.) R. L. L. Hart, relinquishes the act. rank of Maj on ceasing to be empld. (April 1).

### OBITUARY.

JOHN CLAYTON JONES, M.R.C.V.S., Newcastle Emllyn, Carmarthenshire. Graduated, Lond: Dec. 1875. Mr. Jones' death occurred on Sunday, 18th inst.

JAMES EDWARD KITCHIN, M.R.C.V.S., Worship Street, London, E.C. New Edin.: April, 1878.

Mr. Kitchin died at his residence, Glengall Lodge, Woodford Green, Essex, on Monday, 19th inst., aged 64 years.

## INFLUENZA.

Equine influenza, though it has long been widely known and much discussed, is still very imperfectly understood. This was well brought out by Mr. Male's recent paper upon the subject, and especially by the Central Society's discussion of it.

Mr. Male provided a novelty in his suggestion of a possible relationship between human and equine influenza. Of course this is altogether heterodox, and it can hardly be said that Mr. Male has produced much evidence in support of his idea. The mere clinical similarity between the human and equine affections is no great argument, in face of the known fact that some diseases common to man and animals differ considerably in their symptoms and course according to the species of the subject. Again, the coincidence of human and equine influenza has so far been as much controverted as corroborated by other observers. As Mr. Male says, we are not yet in a position to dogmatically deny a relationship between the two diseases; but a strong case against the orthodox view has yet to be presented. Other members may be able to give support to the new view, and any well considered evidence would help matters forward.

Discussion occurred also upon the relation of equine influenza and contagious pneumonia; but not much light can be thrown upon this question by clinicians. We are not likely to get beyond our present doubt until the laboratory provides us with more certain and more accurate aetiological data than we possess now. The discussion upon treatment was more helpful; and perhaps the most interesting point was the generally unfavourable reports of the use of vaccines and sera. The discussion reflected the now general tendency of English practitioners to discard alleged specifics and to rely upon careful hygiene and comparatively simple symptomatic treatment, varied in accordance with the needs of the case. This offers considerable scope to individual judgement, and exchanges of experience regarding it are always useful.

Paper and discussion alike emphasized one important truth. Little as we understand equine influenza, there are few diseases against which a veterinary surgeon with a free hand can do better work under fairly favourable conditions. Every practitioner knows the enormous saving that may be effected by the all-important detection and stoppage of early cases, and subsequent careful clinical supervision throughout the outbreak.

## ON PROFESSIONAL POLITICS.

I have been interested by reading the various views of correspondents on the social status of the veterinary profession, expressed in letters which seem to have been incited by a passing remark of mine, in an article on Propaganda work—that the complaints about the social position of the profession left me quite cold, because each individual member's social position was only personal to himself.

Since there appears to be such a diversity of opinion on the matter, I should like to amplify that statement by expressing the conviction that no profession has any distinct *social* advantage over another, and that the idea that sensible people treat the profession with—as one correspondent puts it—disdain, is in my opinion quite incredible.

One letter quotes another author who refers to the writings of one Vegetius, and on that authority states that 1500 years ago the profession was regarded in Italy as a mean and contemptible occupation, and this author expresses his opinion that public view on the question has undergone little change since. As a matter of fact Vegetius was one of the greatest admirers of the veterinary art that had ever lived up to his day, and he appears to have been betrayed into high flown language solely by his painful conviction that those who devoted themselves to the study of animal medicine were not encouraged as they should be.

Vegetius himself had no mean opinion of the importance of the veterinary art, since he scoured all Italy and Greece to find men best versed in it, and made more use of them in his armies than any commander had ever done previously.

Complaints such as these that the profession is treated with "disdain" and as a "mean and contemptible occupation" at the present day, are not only highly injurious to the advancement of the profession and the proper recognition of our true position, but they are as I believe wholly untrue.

So far as the United Kingdom is concerned, although such drastic statements are still probably absolutely inaccurate, there is ample evidence that the veterinary profession has but very little *political* influence. When we see a sailor calmly in charge of the Animal Diseases Department of the State, and the various other incongruous situations, too numerous to mention, we can only long for the time when another Gilbert and Sullivan will be discovered.

Our disastrous lack of political influence is in my opinion the foundation of every important disadvantage the profession labours under. It limits our sphere of work, it keeps down our fees, it helps quack-

ery, and it allows other professions and laymen to butt into our special provinces to our manifest disadvantage.

As an example of the latter point I may refer to the many articles, letters etc., which have, during the last two or three months appeared in the press, on Rabies. Some were by "our medical correspondent" others by "A Harley Street Physician" or by "M.D.", and by various laymen. I have not seen in any one the slightest mention of a veterinary surgeon in connection with rabies at all; and the general public may be excused if the impression be formed that either the veterinary profession is defunct, or that it has nothing to do with rabies.

When, however, one takes a broader view of the profession, and observes the conditions obtaining in other countries, it is possible to cheer up considerably. In France when they require an expert on the muzzling of dogs, they do not apply to the Navy; and if a young veterinary surgeon wishes for a thorough training in bacteriology he is given it *free of charge* at the Pasteur Institute. He is not given a limited "veterinary course," but he has to study the whole science—and that very thoroughly. If he requires special instruction in Parasitology, Haematology, etc., for research work he can have it at the College de France or the School of Medicine, and no one ever dreams of differentiating, preferentially, between the practitioner of human and animal medicine.

In that country pathology is recognised only as pathology, and it would be hopeless to attempt to move the French mind from that one logical standpoint. Here, we seem to be so beset by extraordinary fads, preferences and fanciful sentiment, that I think the best way the veterinary profession can adopt to avoid being finally smothered in mental fog is to institute a systematised form of propaganda which would ensure the profession being *kept always before the public*.

One need not look very far to see that in other countries veterinary surgeons have attained positions which, in the existing state of things would be practically impossible in the United Kingdom.

Salmon (although he never went to sea) was Chief of the Bureau of Animal Industry in the United States; and his position in the world of scientific medicine is one the profession may well be proud of. Hassal, although a British veterinary surgeon, is responsible for many years of patient work in America, the results of which are well known to, and appreciated by every zoologist of importance in the world.

Gilruth, who was recently indicated in *The Record* as being now the Governor and Administrator of the Northern Territory of Australia, was for many years chief of the Veterinary Department in New Zealand, and while holding that office he was also Pathologist and Bacteriologist to the British Medical Association, and during the outbreak of Bubonic Plague, was Plague Commissioner.

When any veterinary surgeon in the United Kingdom receives appointments similar to the two latter, I, for one, shall be confidently watching for the advent of the millenium.

I had the honour of illustrating Gilruth's report on Bubonic Plague, and about 10 years ago I met Haffkine in Paris, who referred to it as a classic report in the history of Plague. I may as well admit at once he was referring to Gilruth's work, and not to my elaborate frontispiece.

Gilruth's other work in animal diseases is well known, and to my personal knowledge is often quoted on the continent as well as in American literature, and is better known in most countries probably than in the United Kingdom.

Reakes the Chief Veterinary Officer to the Government of New Zealand is not only the head of the Veterinary Department but he is also Director of the whole Stock Department; a position of affairs which may usefully be recommended for study to the British Minister for Agriculture.

Chauveau, to mention only one of the many distinguished French veterinary surgeons, was President for many years of the largest Pathological Society in the world, and he was a member of the examining boards of both the medical and veterinary professions. Although Chauveau was a veterinary surgeon he is regarded as one the most distinguished scientists of his day.

One might continue for a long time to refer to men who by their work and example have made the profession known and respected as an intellectual and scientific occupation, and such world-wide facts are not to be disregarded by practical people. Much less can they be discounted by injudicious and injurious statements regarding what some people erroneously imagine to be "public opinion."

If in the United Kingdom our peculiar sentiments and prejudices so blind us to what has been done elsewhere that we can only see the profession as it appears here—lacking in influence, apathetic, and unable to make itself heard when others try to teach us our business, we may eventually persuade ourselves that there is something inherently vulgar and wrong in the study of animal diseases and in the relief of animal suffering.

I am, however, very glad to see from a letter by Mr. St. Bel Gollidge that there is at any rate some indication of a spirit abroad, the judicious use of which would soon ensure us that sound political position we and our predecessors have long ago very justly earned.

HENRY C. WILKIE, F.R.C.V.S., F.Z.S.

#### COLONIAL APPOINTMENTS.

Now that many young members are likely to be demobilised and may desire to try their fortunes in the colonies, a word of warning may not be out of place. No young man should be tempted merely by the offer of a salary which seems to be higher than he could obtain in the mother country. There are many points to be considered in this connection, *e.g.* (1) what is the relative cost of living, (2) what status does the profession enjoy in the country offering the appointment, (3) is the profession protected against quackery.

In the case of Government Services, a salary adequate to compensate for the risks encountered, with a satisfactory pension should be insisted on. The veterinary profession is one, *Vis unita fortior*, and it will be no help to men at present in government service who are trying to raise their status, if young graduates from the mother country are obtainable at a low salary.

In South Africa, to quote a case in point, many good men have recently resigned their posts under the Union government, owing to their dissatisfaction with the prevailing conditions. The Minister of Agriculture is informed and advised by a secretary for Agriculture who, as a layman, cannot be competent to advise on matters connected with the veterinary service. Yet he has a veto on all recommendations, not only with regard to conditions of pay and promotion within the service, but also on recommendations made by the service for the more efficient carrying out of their work.

It is understood that the scale of salaries has recently been improved, but the salaries offered are far from adequate, and strong representations are being made by the veterinary staff in South Africa to the Commission on the Public services now sitting, to remove their grievances. Meanwhile it will strengthen the hands of our members in their fight out there if applicants for Government posts insist on being granted the same status and salary as are now being petitioned for by the present staff. South Africa is a rich and growing country, and it will find it to its advantage to increase its staff of qualified veterinary surgeons, even to three times its present number, and to offer such conditions of pay and pension as will attract the best class of candidate.

Let this not be to discourage young men from emigrating. There is a certain type of man—and happily, the mother country produces a good few of them to build and strengthen her empire—to whom the uncertainties of colonial life are infinitely preferable to the unadventurous routine of general practice at home. These will not be deterred from seeking their fortunes abroad, and this note is written merely to remind them of the duty they owe, as members of a learned profession, to those who have gone before.

#### A SIGNAL FLAG METHOD.

Having an extensive country practice in a wide district, I have for the last ten years used a flag system with great benefit to myself. I used to find it very annoying, often passing through a village, to find a telegram awaiting at home to go to the next farm. So I arranged with clients at any time they wanted me, to put up a small flag where it could be seen from the road. If urgent, send a message; if not, I could call when passing. They became quite enthusiastic about it, and I can tell their politics by their flags, as most conservatives use a blue, and liberals a red. I was passing through an Oxfordshire village the other day and when I returned I found a farmer had tied a piece of news-

paper on the end of a stick and tied it to a gate post. I can thoroughly recommend this practice as a saver of time, petrol and temper, and it costs nothing to work.

Faringdon.

J. H. PARKER, M.R.C.V.S.

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### CAMPHORATED CARBOLIC OINTMENT IN THE TREATMENT OF FOLLICULAR MANGE.

Slavu published an account of this treatment in the *Arhiva Veterinara* of 1914. As carbolic acid is a good anti-parasitic agent, he has attempted to use it and at the same time to correct its irritant and coagulating effects upon albumen. With the latter object he has mixed it with camphor, which is also a parasiticide. He has used an ointment composed of one part liquid carbolic acid, two parts ordinary refined camphor, and twenty parts white vaseline, applied after the following technique.

The animal is clipped, even when the affection is localised; otherwise diseased parts might pass unperceived. The surface of the body is divided into four areas for the purpose of treatment. Each day one of these parts is well rubbed with the ointment; and thus, at the end of four days each has been treated in succession. The animal is next bathed with a 2% solution of sulphurated potash, and the whole process is then repeated. This goes on until each of the four divisions has been treated with the ointment three times in slight cases and four times in serious ones.

In pustular follicular mange, it is absolutely necessary to extract all the pus from the diseased parts before applying the ointment.

If too much ointment was used and if the body was divided only into three parts for treatment, toxic manifestations have appeared; but these were not serious.

Slavu has thus treated twenty-four dogs in which follicular mange had been diagnosed with the microscope. They were of various breeds (bull-dog, fox-terrier, pointer, etc.), and the ages ranged from eight months to two years. Of these twenty-four dogs sixteen had the squamous form of the disease, localised in four cases and generalised in twelve. Two others had the papular form; and the remaining six had the pustular-squamous form generalised.

With the exception of one dog which died of distemper during the treatment, all the animals treated did well. They increased in weight, the skin regained its suppleness, the hair grew again, and after from nine to sixteen days of treatment the parasites had disappeared. No recurrence of the disease was manifested, even four months after the cessation of the treatment.

The effect of the ointment is due as much to the carbolic acid as to the camphor. The camphor plays an important part as a parasiticide; for, with camphorated ointment alone, Slavu succeeded in curing sarcoptic mange and even follicular mange, though by a more prolonged treatment.

The ointment of camphorated carbolic acid is superior to carbolic ointment, because it does not cause any modification in the structure of the skin viewed microscopically, and it enables the medicament to penetrate and to come into contact with the parasites.—(*Annales de Médecine Vétérinaire*).

W. R. C.

#### NATIONAL ASSOCIATION OF VETERINARY INSPECTORS.

A meeting of the Council of the National Association of Veterinary Inspectors was held at the Grand Hotel, Birmingham, on Wednesday May 14th, 1919, at 2 p.m. Present. Major Abson, D.S.O., President, (in the chair) Messrs F. W. Garnett, John Malcolm, R. C. Trigger, J. Brennan de Vine, H. J. Dawes, and the Hon. Sec. The minutes of the last Council meeting were read, confirmed, and signed by the President. Letters of apology for absence were read from Messrs George E. King, T. H. Duckworth, Lieut.-Col. Brittlebank, C.M.G., John Dunstan, R. D. Williams, Hugh Begg, James Crowhurst, F. L. Gooch, P. G. Bond, and W. W. Grasby.

Mr. JOHN MALCOLM proposed a resolution, placing on record the Council's appreciation of the distinguished services to the State which had been rendered by its President, Major Abson, and Hon. Treas. Lieut.-Col. Brittlebank, during the war, and which have been graciously recognised by His Majesty the King in the bestowal of the D.S.O. and C.M.G. respectively. This was seconded by Mr. R. C. Trigger, supported by Mr. H. J. Dawes and carried with acclamation.

Major ABSON, D.S.O., replied expressing his sincere thanks for the appreciative remarks of the proposer and others, and continuing, mentioned the various causes which had led to the suspension of any active operations by the Society during the war, and expressed his conviction that the need for such a Society was greater now than ever, and that the next year or two promised to be a critical time for veterinary inspectors, unless a combined effort were made by them to safeguard their interests under the new legislative measures which were before Parliament.

Mr. H. J. DAWES proposed a resolution placing on record the loss felt by the Association owing to the death of several members since the last meeting. This was seconded by Mr. F. Garnett and carried. The Secretary was instructed to communicate with the Secretary of the R.C.V.S., in order to obtain a complete obituary list.

The names of the following gentlemen were proposed and seconded to fill five vacancies on the Council, namely, Messrs J. Brennan De Vine, (one of the Hon. Auditors) J. G. Parr, Leicester, G. Dudgeon, Sunderland, W. Ascot, Bideford, and J. O. Powley, Victoria Road, Sutton Coldfield, the last named gentleman having been elected a member of the Association on the proposition of Mr. Malcolm, seconded by Mr. Dawes.

Mr. MALCOLM proposed that Messrs Powley and De Vine be the Hon. Auditors, Mr. Powley, being elected in the place of Mr. W. S. Carless, deceased.

Mr. GARNETT proposed and Mr. Malcolm seconded the proposition that the Council and officers, with the above additions to fill death vacancies, be re-appointed, en bloc.

#### MEETING AT NEWCASTLE.

On the proposition of Mr. Malcolm, seconded by Mr. Garnett, it was decided that the next annual meeting of the Association be held at Newcastle-on-Tyne, on Thursday July 31st, at 3 p.m. This arrangement has been made to coincide with the annual meeting of the Royal Sanitary Institute, the Veterinary Section of which will

be presided over by Mr. John Malcolm, F.R.C.V.S. The meeting of the Veterinary Section of the Royal Sanitary Institute will be held on August 1st, and an address and a demonstration given by Sir Stewart Stockman on "Rabies." The arrangements as to the meeting were left in the hands of the President, Mr. Malcolm, and the Hon. Sec.

Mr. J. Brennan De Vine kindly promised to read a paper at the annual meeting on "The position and prospects of veterinary inspectors during the period of National Re-construction."

#### FEES BY LOCAL AUTHORITIES.

A long discussion took place on the revision of fees payable by County Councils and other Local Authorities, and it was decided on the proposition of Mr. H. J. Dawes, seconded by Mr. R. C. Trigger, that members of the Association be urged to apply to their local authorities for an increase of fees up to the following minimum scale, which is now in operation in the West Riding of Yorkshire.

For each visit and inspection.	£1	1	0
For the second and every other visit on any other day if on the same round as the first	10	6	
If not on the same round	1	1	0
Re-inspections. (including Parasitic Mange)	10	6	
For post mortem examination or Microscopical examination of blood.	1	1	0

Mileage in all cases 7½d. per mile each way (or 1/3d. per mile the double journey) from Veterinary Inspector's residence.

#### BOARD OF AGRICULTURE FEES.

The question of fees paid by the Board of Agriculture and Fisheries to Local Veterinary Inspectors was raised and discussed and several recommendations made.

The Hon. Sec. was instructed to advertise in the two weekly Veterinary papers asking all veterinary inspectors to become members of the Association.

Kettering, 24/5/19. TREVOR F. SPENCER Hon. Sec.

#### PROGRESS OF VETERINARY WORK IN INDIA.

"Report on the progress of Agriculture in India for 1917-18" is to hand, published at Calcutta, with a short introduction signed by the Agricultural adviser to the Government of India, Mr. J. Mackenna. It runs to 235 pages, including 30 pages of tables of appendices, and is essentially a review of the position of the many departments coming under the head of Agriculture. Chapter V., upon veterinary progress, from which the following excerpts are taken, occupies 30 pages, and, in addition to the two sections here quoted, Administration and Inoculation, includes Cattle and Sheep-breeding, Veterinary Education and Research.

Reports from the various provinces have appeared in our pages when space has allowed, but this grouping of the Provinces gives a fuller impression of the magnitude of the Department and its work. The perennial difficulties become even more prominent—Understaffing: unattractive conditions of service: ignorance and indifference to the natives—with hopeful results in a few provinces.

"The department is much understaffed and considerable expansion is necessary if prophylactic measures for the cattle, which are the backbone of the Indian cultivator's prosperity, are to be provided on an adequate scale. Much educative work requires to be done in the districts by the veterinary staff before people will begin to understand the ways in which contagious diseases can be avoided and kept under control. This can only be achieved if more staff is provided."

[The following short notes show, *inter alia*, how military service has interfered with the work of the Department, and how the work has steadily increased in volume.]

**Bombay.** Colonel G. K. Walker, C.I.E., held charge of the department throughout the year. Out of the subordinate staff of 89 men 5 were on military duty and 8 posts were unfilled.

**Madras.** Mr. Aitchison, Principal of the Madras Veterinary College, held charge of the office of Superintendent in addition to his own duties from the 1st April, 1917, to 12th November, 1917, when Mr. F. Ware, the permanent Superintendent, again took over charge. The post of Second Superintendent sanctioned by the Secretary of State could not be filled on account of the war.

**Bengal.** Lieut.-Col. A. Smith remained in charge of the department in addition to his duties as Principal of the Bengal Veterinary College. The total number of Assistants doing military work during the year was eight.

**Bihar and Orissa.** The department was under the charge of Mr. D. Quinlan throughout the year. Of the subordinate staff three were on military duty. It is reported that as the conditions of pay are not satisfactory candidates for the service have been few and ill-qualified. The Local Government have submitted proposals to the Government of India for a great increase in the supervising staff and more attractive conditions of service for all branches of the department.

**United Provinces.** Mr. E. W. Oliver returned from leave in September, 1917, and took over charge from Mr. S. G. M. Hickey, Second Superintendent, who was officiating for him. Twelve members of the subordinate veterinary establishment were on military duty during the year under review.

A vernacular veterinary journal is issued monthly by the Society formed by the subordinate staff of the department.

**Punjab.** Colonel Farmer, C.I.E., held the post of Chief Superintendent throughout the year. Two Inspectors and 37 Assistants were working in the Military Department.

That the Veterinary Department in the Punjab is growing in popularity is evident from the fact that whereas in the quinquennium 1900-05 only 30,000 animals were treated in the hospitals, the number rose to an average of 146,000 in the quinquennium ending in 1910, while in the year under report the number of animals treated was 360,000. A further sure sign of the steady growth of appreciation shown by stock owners is the fact that the people themselves are beginning to build veterinary hospitals, and cattle insurance is also coming into favour. The department is steadily working for the improvement of cattle-breeding and there are now 1087 stud bulls at work in the province, an increase of nearly 10 per cent. on the figures for last year.

The Punjab Veterinary Association continues to flourish. Its Journal has been considerably improved and is a very valuable contribution to the vernacular veterinary literature of the country.

**Burma.** Colonel G. H. Evans was in charge of the department throughout the year with Mr. Rennie as Second Superintendent.

As regards preventive inoculation and the so-called readiness of the Burman cultivator to have his cattle inoculated, Colonel Evans makes the following remarks: "There may be an impression that cattle-owners in general jump at the opportunity of free serum injection for their cattle; if this is so, it is a fallacy. Very few are really desirous to have it done. Much tact, patience, chaff, etc., is often necessary to induce Burmans to grant

consent. With them in my opinion the chief obstacle is laziness; they hate bringing their cattle, waiting their turn, or giving a hand. If the job can be done while they sit around and smoke they don't mind. With Indians the case is quite different. They do not wish to have anything done, or be interfered with.

"When cattle are injected it is usually hopeless getting owners to mix their cattle with sick ones; they prefer to take their chance of animals contracting disease later. We have injected many animals two or three times owing to fresh cases being introduced, but, generally speaking, one injection is all owners will submit their cattle to."

**Central Provinces.** Mr. C. W. Wilson held charge of the department throughout the year. The post of Second Superintendent was vacant. Fourteen Inspectors and Assistants were on military duty.

It is gratifying to note that the department is gaining, more and more, the confidence of the people. In two years the number of cases treated by Veterinary Assistants has risen from 267,676 to 444,104.

**Assam.** Mr. W. Harris held charge of the department throughout the year. The subordinate staff was strengthened by the appointment of four new Assistants, bringing the total number to 41.

**North-West Frontier Province.** On Mr. Meadows services being placed at the disposal of the Army Department, Mr. T. F. Quirke held charge of the department in addition to that of North Punjab. One-fourth of the sanctioned scale of the subordinate veterinary staff was on military duty.

**Sind, Rajputana and Baluchistan.** Mr. J. A. G. Cattell held the post of Superintendent throughout the year, except for 13 days in March when he proceeded to Quetta for training in the Army Remount Department, Baluchistan Circle, and Khan Bahadur S. G. Haji, Deputy Superintendent, acted for him.

**Imperial Bacteriological Laboratory.** During the year under review the output of the products of this laboratory was increased to nearly double that of last year.

To meet the increasing demands for anti-rinderpest serum and to maintain rinderpest virus for use in the inoculation of animals at the military dairies, the branch laboratory at Barseilly was opened during the winter months and 404,847 doses were prepared there. During the year the demand for mallein from the Military Department increased enormously, but all indents were complied with.

Amounts of sera and vaccines manufactured at this laboratory and issued during the year 1917-18.

Name of product	Doses prepared 1917-18	Doses issued	
		1917-18	Average of previous 5 years
Rinderpest serum	2146421	2069961	1127540
Anthrax serum	14175*	19727	25020
Hæm. Septicæmia serum	216457	189428	84311
" " vaccine	117124	117124	127890
Blackwater vaccine	*	17324	16700
Mallein	191747	193147	26323

\* Prepared according to demand.

The total value of the different products calculated on the basis fixed by Government amounted to Rs. 415,080 (£27,672) against an expenditure of Rs. 336,481.

Besides serving the needs of India, this laboratory undertook to meet the request of (1) the Ministry of Agriculture, Cairo, for a supply every month of 50,000 doses of anti-rinderpest serum up to December, 1918, and (2) of the Veterinary Department of the Sudan, for 200,000 doses of anti-rinderpest serum to be supplied before September, 1918.

## PREVENTIVE INOCULATION AND LEGISLATION.

A comparison of the figures of mortality among cattle in India from rinderpest alone during the last three years, namely:—

1915-16, 95159; 1916-17, 115548; 1917-18, 143861

indicates that the ravages of rinderpest are on the increase and, even allowing for the fact that the improved system of reporting outbreaks now in vogue has resulted in a large increase in the number of deaths notified, it is permissible to enquire how it is that in spite of the increasing number of inoculations performed we are unable to stamp out the disease or minimise its ravages. The greatest difficulty in this direction is the apathy, stubbornness and ignorance of the villagers. They do not sufficiently understand the contagious nature of the disease and the ruinous results which follow from their neglect of ordinary precautions. They have not yet grasped how much isolation and disinfection help to check the disease. Further, the unrestricted movements of animals from infected areas and absence of compulsory inoculation of all cattle in the affected village and those surrounding it, are the causes most responsible for the spread of the disease. In this connection it would be well to emphasise the fact that rinderpest is a disease which *can* be stamped out and prevented from again occurring in any district, if proper veterinary police methods are employed, the reason being that the virus which causes the disease is propagated almost exclusively in the bodies of ruminants.

There is no such thing as a spontaneous outbreak, because it can always be proved that the disease is at the time prevalent somewhere in the neighbourhood and that it has been brought to the affected village either by animals suffering from the disease or by infected material.

Among the principal methods by which cattle can be protected from rinderpest are (1) the serum alone method, (2) serum and simultaneous method, (3) isolation and disinfection, and (4) inoculation with bile. The first method has been accepted as the best for India on account of its simplicity and absolute safety, and consists in the injection of a suitable dose of serum calculated according to the body weight and susceptibility of the animal. The injection of this dose of serum does not give full protection for an unlimited length of time and is used with the object of raising the power of resistance of the animals which are exposed to infection, by neutralising the causal agent, so that if they are attacked during the period of immunity they get only a mild form of the disease and become after recovery totally immune for life. The serum alone method should always be used with powers of compulsory inoculation and isolation. In order that its application in the field may be effective, all animals must be inoculated at the same time both in the affected village and in the villages in the neighbourhood, so that the site of the outbreak of the disease may be surrounded and isolated by a barrage of immunised animals, and, by the time the immunity conferred on them by the serum has disappeared, the disease will have also died out from lack of a suitable host.

This was the plan of campaign employed in South Africa, together with the simultaneous method, to stamp out the disease there. Power was placed in the hands of the controlling authority to inoculate and isolate all animals compulsorily, and the ignorance and prejudice of one owner was not allowed to endanger the stock of the neighbourhood. By these means South Africa was freed from a devastating scourge.

The Superintendent, Civil Veterinary Department, Madras, writes as follows:—

"After an extended trial in this Presidency, it must be admitted that the 'serum alone' method of inocula-

tion will not stamp out rinderpest in this country, while the conditions under which it has to be used in the villages remain as they are.

"Nothing less than compulsory inoculation will give the serum a fair chance, for, in a typical village, rarely as many as two-thirds of the cattle are produced for inoculation, and although the staff has been instructed repeatedly to return to every village for purposes of re-inoculating those animals which have already been done, the ryots get tired of producing them once a month, and when the animals eventually contract the disease from some of the uninoculated ones, and perhaps die, the serum is blamed.

"The result may be that eventually the ryots of that and other adjacent villages lose faith in the serum, refuse inoculation and re-inoculation altogether, and the disease goes on as if this department had made no effort at all in the matter."

In connection with surra also, the necessity for legislation is pointed out by Mr. Oliver, Superintendent, Civil Veterinary Department, United Provinces, in the following passage:—

"The spread of surra from its endemic areas in the tracts along the foot of the hills to the districts of Etawah, Mainpuri, Banda and Nainital, was due to the unusually extensive transport operations and frequent movements of animals during the past two years. In addition to these causes we must consider the yearly increasing facilities for travel and development of commercial intercourse between distant parts of the country, and it is easy to foresee a still further spread of infection unless energetic prophylactic measures are introduced without further loss of time. Whatever line of action is contemplated it is all important that the preventive measures taken must be swift and thorough. I am strongly of opinion that if we are to avert such a catastrophe as that which occurred in Mauritius in 1902-03, more effective legislation than at present exists should be introduced at once. In 1910, it was decided that, with certain modifications and at the discretion of Local Administrations, the Glanders and Farcy Act could be applied in cases of surra, but although this was introduced in the case of the United provinces, in some of the adjacent territories and provinces no active steps in this direction were taken. It is obvious that compulsory slaughter of all diseased animals, and isolation of suspected cases and 'in contacts' is one of the first and most important measures to be adopted, but if this rule is only enforced here and there the result cannot be anything but a costly failure. The Surra Act or a modified or amended form of it should be applied without exception throughout the whole of India. Next in importance to the destruction of all affected cases is the more complete control of the movements of all animals in the diseased localities, and powers should be acquired to declare affected areas, and, where necessary, to prohibit ingress and egress to and from such places. Rules for the closing of fairs and the prohibition of animal traffic on certain highways, if desirable, might be considered."

In this as in many other diseases the increase in the spread of infection has become very marked and it is most important that similar methods of control should be adopted throughout all India. A policy of control confined to a district or a province is a policy of half measures at which the disease will laugh.

## THE R.A.V.C. COMFORTS FUND.

## Alteration of Date of Meeting.

The Meeting of the Contributors to the above Fund notified for Tuesday, 3rd June, at 3 o'clock, is postponed to Wednesday the 4th June, at the same hour.

## THE INFLUENCE OF DIET ON TEETH FORMATION.

Some few years back there was a good deal of attention given to the question of "Rickets" in puppies, and a paper was contributed at one of the meetings of "The National" by Mr. F. W. Cousins, M.R.C.V.S. No definite conclusions were arrived at, although lack of exercise was credited with being at least a contributory cause. At that time the word "vitamines" was not invented, although some of the effects of diet were fully acknowledged. The following extracts are from the report of an Experimental Study, by May Mellanby, from the Household and Social Science Department of the London University, Kensington, to the Medical Research Committee.

The details of the experiments and a dozen illustrations of the defective teeth are omitted; but enough of the results and the line of argument are given to show a direct connection of cause and effect.

"The investigation was undertaken primarily with the object of studying—

1 The factors involved in the development of sound teeth and of the growth of the jaws in relation to the size of the teeth.

2 The factors bearing on the immunity of erupted teeth to caries and other diseases.

I propose to describe experimental work which deals with the first of the above problems and will adduce evidence to show that—

1 Hypoplasia of the teeth is caused largely by a deficient diet.

2 The factor in the diet which controls the calcification of the teeth is something of the nature of an accessory food factor (vitamine).

3 This factor has a similar distribution to that of fat-soluble A, and has recently been shown by E. Mellanby to be largely responsible for the calcification of bone, a deficiency of this substance in the diet being followed by the development of rickets.

"The part of this work to be described here has involved the examination of the teeth of those puppies used by my husband, Dr. Edward Mellanby, in the course of an extensive research on rickets made for the Medical Research Committee. Suffice it here to say that the diets consisted chiefly of white bread and separated milk, about 200 c. cm. per diem, together with the substances to be tested.

For work of this nature domesticated dogs are eminently suitable. In the first place because their normal diet is very similar to that of man, and in the second place because the formation and development of their teeth is more comparable with his than is the case with most other available animals.

In examining the jaws and teeth attention has been paid to the study of (1) the time of shedding of the deciduous teeth; (2) the time of eruption of the permanent dentition; (3) the arrangement of the teeth in the jaws; (4) the condition of the enamel, &c.; (5) the calcium content of the teeth.

## RESULTS OF EXPERIMENTS.

Three puppies of the same litter, when approximately 8 weeks old were put on to diets the only differences in which were that (a) contained 10 g. of cod-liver oil per diem, (b) 10 g. of butter, and (c) 10 g. of linseed oil. The puppies were killed 15 weeks after the diets were started. It will be observed that (a) has lost all its deciduous teeth, while all the permanent teeth are fully developed; (b) comes next in order—here some of the deciduous teeth are still firm in the jaws, while the permanent teeth are not all erupted; (c) is still further behind, both as regards the shedding of the deciduous and the eruption of the permanent teeth. The arrangement of the teeth

in the jaws is also better in (a) and (b) than in (c). The condition of the enamel varies in each case, appearing perfect in (a), slightly defective in places in (b), while in (c) the enamel on that part of the crown near the neck of the incisors is dark brown and that on the carnassials, except the top of the cusps, is dull brown."

"These experiments and others of the same type show that when linseed oil is the only fat in the diet, then there is a delay in the shedding of the deciduous teeth and in the development of the permanent dentition. The animal fats, and more particularly cod-liver oil, cause these changes to proceed in a normal way. Again, the arrangement of the teeth and their appearance is much better when animal fats have been eaten."

"As a general rule, it is difficult to associate rapid growth with ill-health, and yet we have seen in these experiments that the teeth of the more rapidly growing puppies are worse, whether the comparison is confined to the same or to another family. It seems impossible, therefore, to escape the conclusion that the malformed teeth are the result of some specific influence of the diet, such as has been suggested."

"It is always possible that chewing hard crusts, bones, etc., may improve the circulation in the developing jaws and so cause better teeth formation, but it cannot explain the results described in this paper, for in no case was hard food of any kind given. From the point of view of bacterial action and the production of toxic products, the diets would appear, in most cases, to be similar, except in so far as the fats are concerned."

What, then, is the factor (or factors) in the diet responsible for these changes? We have seen that the puppies fed on animal fats such as cod-liver oil, butter, and suet had the best teeth, whereas those fed on linseed oil had the worst. There is evidence that other vegetable oils—for instance, arachis oil and cotton-seed oil—also have deleterious effects.

As has been already suggested, the metabolic factors normally involved in the process of teeth development may be of the nature of accessory food factors. It is now recognised that fat soluble A is present in abundance in cod-liver oil, butter, and animal fats generally, and is deficient in vegetable fats. The whole subject of accessory food factors and the part they play in health and disease is in its infancy, and therefore cannot be accepted as explaining in an unquestionable way facts such as are here described. But for the want of a better mode of expressing the general results of these experiments, one may say that a deficiency of fat-soluble A in the diet is accompanied by abnormal development of the teeth.

A child's diet is most likely to be deficient in fat-soluble A from the ninth month to about the second year of its life; that is, at the transition period between a complete milk diet and one approximating to that of the adult. The permanent teeth calcifying at this period are the incisors, the canines, and the first molars, and it is just these teeth in children that are most commonly hypoplastic and carious.

Since rickets is commonest in children during these early years, it has been suggested by Dick and others that this disease is the cause of these special teeth being so commonly defective. The work described in this paper, taken in conjunction with the experiments of E. Mellanby on rickets, puts on to an experimental basis the intimate connexion between this disease and hypoplasia of the teeth."

"If the accessory food factor theory is the real explanation of the facts described in this paper it ought to be possible to produce similar changes in the deciduous teeth of puppies by feeding a pregnant bitch on those diets which have been shown to prevent normal tooth development in young animals. Experiments on these lines are now being carried out."

"On the accessory food factor theory one can also understand why the Esquimaux in his own country, where flesh and blubber are the staple articles of diet, has such excellent teeth, while the inhabitants of Chili, who live chiefly on cereals, have teeth which are much less sound.

There is no doubt that our modern dietary is harmful as far as the teeth are concerned, and, if the results of the present work and the deductions made are correct, the teeth of the people of this country will tend to become worse, unless our diet consists in the future more of whole milk and other foods containing fat-soluble A and less of bread, rice, potatoes, etc., which are deficient in this factor.

#### SUMMARY OF RESULTS.

1 A diet containing in abundance those articles with which the fat-soluble A accessory food factor is associated—e.g., cod-liver oil, butter, &c.—allows the development in puppies of sound teeth.

2 A diet otherwise adequate but deficient in the substances with which fat-soluble A is associated brings about the following defects in puppies' teeth: (a) Delayed loss of deciduous teeth. (b) Delayed eruption of the permanent dentition; in some cases the delay in the eruption of the permanent teeth is more marked than the delay in the loss of the deciduous teeth. (c) Irregularity in position and over-lapping, especially of the incisors. (d) Partial absence of or very defective enamel. (e) Low calcium content; the deficiency in calcium salts may result in the teeth being so soft that they can be cut with a scalpel.

3 The evidence makes it clear that this is an instance of diet affecting the teeth from the inside, and is independent of bacterial sepsis and other oral conditions associated with food.

4 These results cannot be considered as being due to acute illness or "malnutrition," for (a) the improvement to the teeth by the addition of fat-soluble A containing substances (animal fats, etc.) is as characteristic as the deleterious effect of a deficient diet; (b) there is evidence that the defective teeth are most pronounced in the rapidly growing puppies, and it is difficult to associate rapid growth with illness or "malnutrition," as generally understood.

5 This work, taken in conjunction with the experiments of E. Mellanby on rickets, puts the close relationship between hypoplastic teeth and rickets on to an experimental basis.—*The Lancet*.

#### NON-PROFESSIONAL INSPECTORS.

Sir,—The article in the V.R. of the 10th inst., on non-professional inspectors constrains me to pen a few remarks on the subject.

The fault of the Board of Agriculture in the past has been too much administration by men "Born to Rule," and not sufficient practical advice to stock-owners by veterinarians fully conversant with their subject.

With reconstruction in the air, and the cry of economy and efficiency ringing through the services, the time is opportune to replace the so-called Lay Administrator with the practical veterinarian. The resulting increase in efficiency, saving of public funds, greater security to the stock-owner, and the general uplifting of the profession when the curbing yoke of lay interference with purely professional matters is once removed can hardly be estimated.

*Punch*, some years ago, very aptly and tersely described the Inspector of the Board as follows:—"To the Agriculturist he poses as the scientist, and to the scientist as the agriculturist."

The opportunity some time ago presented itself of discussing the Board's Secretary (Sir Daniel Hall F.R.S.)

with one of the Board's Laymen, and when it was suggested that the appointment of a scientific agriculturist was a step in the right direction, the reply I got was "Oh! he's *only* a scientist." The inference I was left to draw from the tone and general demeanour of the inspector was, that because Sir Daniel Hall was unfortunately a scientist it was not possible for him to be an administrator.

The old erroneous idea of "being born to rule" still obtains with the lay staff of the Board, and it is up to the profession generally (and not least the Veterinary Staff of the Board) to disabuse the Lay mind by both word and deed.

To quote only one case of overlapping and trespassing going on between veterinary and administrative work:—A horse belonging to a farmer friend contracted mange. In due course the farmer was visited by a Lay inspector of the Board who "inspected" the animal. The owner pointed out the horse in the adjoining stall as having become infected, whereupon, the inspector examined the animal and said "Oh no! that's *not* mange." Comment is needless.

As a suggestion, I throw out to the National Association of Veterinary Inspectors that a discussion on the subject of the present use of non-professional inspectors might serve some useful purpose in devising means of combating the evil. At the same time it would be as well to point out that so far as the writer is aware, the profession as a body has, in the past, taken practically no action to combat the appointment of lay inspectors, with the result that in framing their Acts and Orders the Board of Agriculture invariably arranges for all administrative work to be carried out by non-professional inspectors.

The appointment of Veterinary inspectors by the Board of Agriculture (to replace the present Lay Inspectors) working in collaboration with the local practitioners, suggests the only means of defeating and ousting the non-professional inspector.

The constitution of the Board of Agriculture seems to be but little understood by the rank and file of the Profession, and an article on the subject in your valued journal might be beneficial.

I am afraid I have written at greater length than was originally intended, but the subject being vital to the the Profession needs no apology.—Yours faithfully,

May 21st.

"NUNC AUT NUNQUAM."

#### ANÆSTHETICS.

To the Editor of the "Veterinary Record."

There are probably few British Veterinary Surgeons who will not welcome, as a great advance, the Animals Anæsthetics Bill, if it becomes law. A few points I should like to see discussed however, namely:—

1 *Docking*. It is proposed to add this operation to those requiring either general or local anæsthesia "of sufficient power to prevent pain." I should be glad to know the method of local anæsthesia which can be painlessly adopted to prevent pain in this operation, as it seems to me that four submuscular injections would be necessary (or one intraspinous injection) and it appears to me that these would be more painful than the swift, skillful guillotining of the tail itself. I have discarded searing, which used to be the most painful part of the operation, in favour of ligaturing the arteries and bandaging, and I must say that by this method docking hardly justifies the discomfort to the patient of any method of anæsthesia that I can think of. Note that pain has to be prevented, not merely deadened. I think this operation should either be left out of the Bill, or prohibited altogether.

2 *Castration*. I see no reason for excluding yearlings from the Bill and I am in favour of including all equine

castration in the first schedule. Injuries to the back can be prevented by chloroforming standing, or by the use of the Australian casting tackle which leaves one hind leg free, and gives the colt no purchase to injure himself. Castration standing is both efficient and popular, but is extremely painful, and therefore should be abolished in favour of anaesthesia.

3 *Neurectomy.* This appears in the third schedule. Why not the first? Can anyone prevent (not merely deaden, but prevent) pain in this operation by local anaesthesia? I think general anaesthesia should be compulsory.

4 *Enucleation of eye-bull.* The same remarks apply as under Neurectomy.

Perhaps the gentlemen who advised the promoters of the Bill will please inform me how pain is to be prevented by local anaesthetics in Docking, Neurectomy, and Enucleation of the eye-ball; as I should like to apply their methods, if it can be done.—Yours faithfully,

A. S. LEES.

Stamford. May 25, 1919.

#### THE ROYAL SANITARY INSTITUTE.

Patron: His Majesty the King.

The arrangements for the meeting will include:—

President's Inaugural Address.

Lecture to the Congress.—“*Marine Hygiene*,” by Deputy-

Surg.-Gen. Sir Robert Hill, K.C.M.G., C.B., C.V.O., R.N.

Popular Lecture.—“*The Heritage of Health*,” by Sir Robert Phillip, M.A., M.D., F.R.C.P., F.R.S.E.

Sectional Meetings for the reading and discussion of papers relating to:—

*Sanitary Science and Preventive Medicine.* President—Prof. G. Sims Woodhead, O.B.E., M.A., M.D., F.R.C.P., LL.D., F.R.S.E.

*Engineering and Architecture.* President—Major-Gen. Sir G. K. Scott-Moncrieff, K.C.B., K.C.M.G., R.E.

*Hygiene of Maternity and Child Welfare.* President—Sir Leslie MacKenzie, M.A., M.D., LL.D., F.R.C.P., F.R.S.E.

*Personal and Domestic Hygiene.* President—The Lady Mayoress of Newcastle.

*Industrial Hygiene.* President—Sir Thomas Oliver, M.A., M.D., D.Sc., F.R.C.P., LL.D., D.L.

Conferences:—

*Representatives of Sanitary Authorities.* President—Councillor C. T. Stableforth, J.P.

*Representatives of Port Sanitary Authorities.* President—Alderman G. C. Coates, J.P.

*Medical Officers of Health.* President—Prof. H. R. Kenwood, C.M.G., M.B., D.P.H., F.R.S.E.

*Engineers and Surveyors.* President—T. W. A. Hayward, M.Inst.C.E.

*Veterinary Inspectors.* President—James Malcolm, F.R.C.V.S.

*Sanitary Inspectors and Health Visitors.* Presidents—William Hudspeth and Miss E. Orange.

Among the long list of subjects on which Discussions are being arranged, these directly interesting the veterinary profession are:—“Milk Supply”; “Relation of County and Municipal Veterinary Inspectors to the Control of Contagious Diseases of Animals, and the Fuller Development of a wholesome Meat and Milk Supply”; “Rabies,” (The report of meeting of National Association of Veterinary Inspectors, p. 448, announces that Sir Stewart Stockman will give an address and a demonstration).

Visits are arranged during the Congress to Water Works, Sewage Disposal Works, Isolation and other Hospitals, and other places of Sanitary interest.

#### ROYAL COLLEGE OF VETERINARY SURGEONS

To the Editor of “The Veterinary Record.”

Sir,—I regret to have to report that an unfortunate error has crept into the Voting Papers recently issued for the election to Council. The number of attendances at Committee Meetings made by Mr. A. Lawson is given as 3, but this figure should have been 13. I have not yet been able to trace the cause of the mistake, but can only say that no error occurred in the Register of Attendances kept in this office. I have expressed my apologies to Mr. Lawson, and take this first opportunity of publicly correcting the error, and at the same time of expressing my regret at its occurrence.—Yours faithfully,

FRED BULLOCK, Secretary.

26th May 1919.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919:—

#### REGISTRATION OF FARRIERES.

At a meeting of the Central Executive Committee of the National Farmers Union of Scotland, held in the office of the secretary, Glasgow, Mr. James Gardner, president, in the chair, it was agreed to lodge an emphatic protest against the provision of this Bill, which imposed a disability on farriers and shoemiths who had not served a period of apprenticeship and passed a qualifying examination.

## ANIMALS (ANÆTHETICS) BILL.

The following additions have been made to the Schedules:—

*First Schedule*—Horses. (The following are additions): 7 Amputations of penis, mamma, limbs. 8 Extraction of permanent molar teeth. 9 Operations for scrotal and inguinal hernia. 10 Operations for scirrhous cord and extensive tumours. 11 Trephining.

*Second Schedule*—Dogs and cats. 4 Amputations of penis, mamma, limbs. 5 Operations for scrotal and inguinal hernia.

*Third Schedule*—Bovines. (This is new matter, with the exception of trephining). 1 Ovariectomy. 2 Castration in animals a year old and upwards. 3 Operations for actinomycosis. 4 Laparotomy. 5 Amputation of penis, mamma, limbs. 6 Trephining. 7 Disbarring cattle over six months old.

*Fourth Schedule*—Horses. (The following are additions to the former Third Schedule). 3 Line and point firing. 4 Operation for umbilical hernia. 5 Urethrotomy. 6 Docking of the tail.

*Fifth Schedule*—Dogs and Cats. (This and the following one are new). 1 Enucleation of the eyeball. 2 Operation for umbilical hernia. 3 Urethrotomy.

*Sixth Schedule*—Bovines. 1 Enucleation of the eyeball. 2 Operation for umbilical hernia. 3 Rumenotomy. 4 Urethrotomy.

## Sheep Scab.—Deputation to B. of A.

At a recent meeting of the Council R.A.S.E., the Earl of Northbrook (Chairman of the Committee) reported that a deputation consisting of Mr. Davis Brown, Mr. Alfred Mansell, Mr. Ernest Mathews, and himself attended at Whitehall Place on April 2nd last to interview the President of the Board of Agriculture on the subject of the present state of sheep scab in this country.

He (Lord Northbrook) introduced the subject and suggested that it would be quite possible to eradicate sheep scab in this country as had been done in New Zealand and Tasmania. He understood that eradication of this disease had been accepted by the Board as possible. After referring to the statistics dealing with the outbreaks in this country, from which it appeared that the cases in 1917 were more numerous than in the preceding seven years, and saying that it was an alarming fact that 29 outbreaks had been reported over a widely distributed area from seventeen counties, the hope was expressed that the President of the Board would seriously grapple with the case.

Lord Ernle in reply, had explained that the figures which had been presented should be dealt with, beginning on July 1st. He said it was quite impossible for the Board, without the loyal co-operation of farmers and dealers, to deal successfully with the disease, and unless this co-operation could be obtained the Board could only do what they had been doing to stamp it out. Local authorities had power whenever sheep were brought into a county to order dipping at once, and again after a period of ten days, and that should keep the particular county secure from infection. Hitherto the only practical suggestion received from the "Royal" was that of making the owner responsible. If it were possible to provide the Board with an adequate staff of inspectors, they should be able to see that the extremely perfunctory dipping, at present too often carried on, was effective. The Committee decided that a letter should be addressed to the County Councils Association calling their attention to the powers possessed by County Councils in respect of Orders for dipping of sheep, and of the absolute necessity which existed for the authorities to carry them out.

Lord Northbrook expressed his regret that the deputation to Lord Ernle on the subject of sheep scab had not had a more satisfactory result. Lord Ernle had repeated a good many of the arguments used on a former occasion, and had again pointed out the difficulties existing in the North of Scotland and the islands in regard to the sheep of the crofters. His own impression was that Lord Ernle had not given very deep consideration to the matter, and was perfectly satisfied with the assurance given by the officer of the Board of Agriculture who was in charge of this subject that the Board were doing everything that was possible. The members of the deputation were still of the opinion that the disease could be eradicated, and that it would be eradicated if the Board would give it their serious consideration and take more drastic steps to stamp it out.

Lord Strachie said that when there was an outbreak of sheep scab some years ago he happened to be responsible for the Board of Agriculture in the House of Commons and he had to go very deeply into this matter. He was satisfied that if more stringent regulations were carried into effect it would be quite possible to stamp out the disease. He suggested that if Lord Northbrook would be so good as to bring up the question in the House of Lords a more satisfactory answer might be obtained.

## The Suffolk Horse.

The Suffolk horse may be safely described as the most ancient and the purest breed of our draught horses. The pedigree charts of the Suffolk extend as far back as 1768. The purity of the breed is conclusively proved by the uniformity of colour, the Suffolk is always of a chestnut shade, ranging from the mealy to the brown-black. His height varies from 15½ to 16½ hands; legs flat, short and clean; pasterns strong, with bone of compact quality; shoulders long, rather forward, and peculiarly well suited for draught purposes; hindquarters long, heavy and well coupled with loin and back; the legs well underneath the body, girth large, flanks well dropped, strong neck, well-formed head carried with spirit, the horse in general being long, low, and wide, with a fine amount of quality, and no point jarring against another.

The chief characteristics of the Suffolk are his great drawing power, unusual docility, activity, and longevity. He is more cheaply kept than any other heavy breed; possesses, with an iron constitution, immense power of endurance, and lasts in ordinary work almost as long again as either the Shire or the Clydesdale. Cases have been known where Suffolk mares have gone on breeding when upwards of thirty years old.

The Suffolk breeders were among the first to require a careful examination for soundness at their county show, and it was a prominent member of the Suffolk Horse Society who induced the Council of the "Royal" to adopt a similar rule.

The fact that the horse has never yet been bred in his native home in a sufficiently commercial way, no doubt largely accounts for the comparatively humble position which the Suffolk Punch occupies in the estimation of the general public. He is universally admitted to be the best agricultural horse in the world, and his quickness of action, good temper, and the persistence with which he will tug again and again at a dead pull, added to his endurance and other qualities, eminently fit him for hauling work in our towns and cities. It is an interesting fact that during the Crimean War Suffolks were found to be the only horses good enough at collar to pull the guns into line.

Considerable numbers of stallions have gone to foreign countries and to our Colonies, particularly to Russia, North and South America, New Zealand, Australia and South Africa.—"CESTRIAN" in *Live Stock Journal*.

**Control of "Patent" Medicines.**

Lord Bledisloe, in moving, during the Committee stage of the Ministry of Health Bill, in the House of Lords, to provide that the Minister of Health should not only exercise powers transferred to him, but also new powers conferred on him, informed the Peers that he proposed to add new powers enabling the Minister of Health to institute prosecutions in cases of frauds in connection with patent and proprietary medicines. He had two amendments down, and also proposed to move a new clause empowering the Minister of Health to deal with "the administration of the law governing the advertisement and sale of patent, secret, and proprietary medicines and appliances." In a later speech he reminded the House that he had sat on the Select Committee of the House of Commons which inquired into the whole condition of affairs relating to patent and proprietary medicines—a Committee which sat for three years, and whose conclusions Lord Bledisloe summed up in strong terms. That Committee had recommended that the control of patent medicines should be part of the functions of the Ministry of Health when that was set up.

Lord Sandhurst, replying for the Government, said the subject teemed with difficulty. The Committee referred to had reported that the sale of patent medicines came under six Acts, and under a variety of authorities. To adopt Lord Bledisloe's amendments would merely cumber up the Minister of Health with obligations which he could not fulfil. Dr. Addison authorised him to promise that the whole subject would be considered without delay, and proposals made to Parliament for whatever new powers were thought necessary.

Lord Buckmaster also spoke of the revelations of the Patent Medicines Report, and Lord Bledisloe agreed not to move his other amendments in Committee. He explained, however, that one amendment proposed specifically to transfer to the Minister of Health the powers possessed by the Privy Council over the qualifications and conduct of dentists, chemists, and veterinary surgeons, and also in regard to the scheduling of poisons.

When the Committee stage of the Bill was completed by the House of Lords on Tuesday Lord Bledisloe did not raise the topic again.

 19 Bank Street, Hillhead, Glasgow  
**Hon. Treas:** Mr. Geo. W. Weir, M.R.C.V.S.,  
 55 Crookston Street, Glasgow  
**Meetings,** Second Wednesday, May, Oct. and January

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1613.

JUNE 7, 1919.

VOL. XXXI.

## THE ANNUAL MEETING.

Like so many of its predecessors, the annual general meeting was a very quiet affair. The attendance was but little better than it was during the war; and no member showed an inclination to start a discussion. There was certainly plenty of material for discussion in the report, which, condensed as it was, was a business-like and informative account of a very arduous and varied year's work. If the disapprobation of the Council's work had been anything like so acute and widespread as some have supposed it to be, surely some members would have been stimulated to attend the meeting and voice it.

The result of the election was not startling. Despite the heavy list of new candidates and the amount of murmuring we have had for months past at societies' meetings and in the veterinary press, the poll was but little heavier than in the two preceding years; which may well be accounted for by the men returned from service abroad. Only one Councilman of the seven that stood for re-election has lost his seat. The two successful new candidates are both well-known men, who on personal grounds would have had good chances at any election under ordinary conditions. It seems impossible to regard the election as anything but a distinct vote of continued confidence in the present Council, and an indication that the supposed dissatisfaction with it has been over-rated. Doubtless there is a good deal of discontent in the profession just now, as there is almost everywhere; but members generally see no reason to seek a remedy in changes of their legislature. In that respect probably they are perfectly right. A larger meeting and a heavier poll would have spoken better for the public spirit of the profession; but the evident decision that no great cause exists to find fault with the present Council is a good sign.

The few words that were spoken upon finance, especially those which fell from the President, deserve careful attention. An official statement that opportunities of advancing the interests of the profession have had to be let pass for lack of funds is worth noting. Voluntary subscription has been a success, and it is a hopeful feature that there is a steady improvement, for so far, every year's total has substantially exceeded that of the year before. This financial year, by its aid, we have almost made both ends meet; but it is clear that we have only done so by undesirable economies on the part of the Council. This ought to be a sufficient stimulus to a further improvement.

Following the suspension of veterinary inspections consequent on the recent disturbances, the Egyptian provinces are now faced with a severe and widespread epidemic of cattle disease.—*Times*.

## THE SEIZURE OF AN ORGAN WHEN ONLY THE ANNEXED LYMPHATIC GLANDS SHOW TUBERCULOUS LESIONS.

Nieberle and Claussen reported their studies of this question in the *Zeitschrift für Fleisch- und Milchhygiene*. Their researches were made upon bovine livers apparently showing an isolated tuberculosis of the attached glands.

Leaving out congenital infection and direct hæmatogenous infection (which, according to Joest and Noack, should be considered as very rare) the hepatic glands are exposed to three modes of contamination. The first of these is direct alteration by the lymphogenous route. Baum's researches show that the bovine hepatic glands are not strictly regional for the liver. They are also in relation with the duodenum, and receive in addition the efferent vessels of the dorsal and ventral glands of the abomasum. The duodenum and the abomasum may therefore intervene in direct lymphogenous infection of the hepatic glands.

The second mode is penetration from a tuberculous centre into the roots of the portal vein.

The third is tuberculous generalisation. The bacilli, having traversed the regional glands of the digestive or respiratory tract, reach first the lesser and then the greater circulation by way of the thoracic duct. They thus gain the liver and are arrested in the hepatic glands.

Direct infection by the roots of the portal vein is very rare. Nieberle has only seen it in disseminated and caseous tuberculosis of the mesenteric glands; and generalisation by way of the thoracic canal is usually anterior to it. Moreover, tuberculosis of the bovine hepatic glands is frequently accompanied by lesions in the lungs, the pulmonary glands, and even in the remote intra-muscular glands.

It is therefore justifiable to conclude that tuberculosis of the bovine hepatic glands is most frequently the expression of a generalised affection, and that it proceeds by the lymphogenous route from the hepatic parenchyma itself.

The authors carried out experiments which corroborate this view. They injected the expressed juice of suspected livers subcutaneously into guinea-pigs, which were destroyed two or three months later. They also cut the livers into very thin slices in order to discover macroscopic lesions. The result of these researches indicated that, in 23% of cases in which tuberculosis is apparently isolated in the hepatic glands, the liver contains tuberculous centres or Koch's bacilli. The seizure of an organ when the corresponding lymphatic glands alone present tuberculous alterations is therefore justified.—*Annales de Méd Vét.*

## ACUTE NICOTINE POISONING IN THE HORSE.

Maire recorded this case in the *Journal de Médecine Vétérinaire et de zootechnie de Lyon*. He was called to a horse suffering from colic, and found it in a condition of very pronounced prostration. The animal showed cold sweats, muscular trembling, abundant salivation, very accelerated respiration, yielding of the loins, staggering gait, infiltrated conjunctiva, projection of the membrana nictitans in front of the eye, and very marked contraction of the pupils.

These two last symptoms especially struck Maire's attention; and, on enquiry, he learned that the horse, an hour before, had been rubbed with a solution of tobacco juice to rid him of lice. Maire immediately diagnosed acute intoxication by nicotine. He bled the horse to the extent of 4 kilogrammes, gave an alcoholised infusion of coffee (1 litre of coffee with 30 grammes of alcohol added), and also gave a subcutaneous injection of 10 centigrammes of pilocarpine. A distinct improvement followed, and it was possible to walk the animal. Two hours afterwards another litre of coffee was given, and also 15 grammes of nitre in solution. The next day, the horse had quite recovered.

A quarter of a litre (1 litre—1½ pints) of tobacco juice had been diluted with about five litres of warm water. Other animals were rubbed with the same solution, but none of these showed any disturbance. (*Annales de Méd. Vét.*) W.R.C.

### Royal College of Veterinary Surgeons.

The Seventy-sixth Annual General Meeting of the Royal College of Veterinary Surgeons was held at the College, 10 Red Lion Square, W.C., on Wednesday, June 4th, Mr. Frank W. Garnett, C.B.E., President in the Chair.

The following members signed the attendance book:—Messrs. W. Reekie, J. McKinna, P. J. Simpson, W. J. Mulvey, A. W. Mason, F. C. Golden, E. A. West, James Rowe, W. Roger Clarke, F. G. Sampson, H. A. McCormack, S. Harrison, Major-Gen. L. Blenkinsop, Messrs. S. H. Slocock, J. Willett, D. J. Davies, G. A. Banham, E. E. Martin, J. J. Aitken, T. S. Price, Sir John M'Fadyean, Mr. G. Thatcher (Solicitor), and Mr. F. Bullock (Secretary).

The Secretary, having read the notice convening the meeting which appeared in the *London Gazette* of the 6th May, 1919, announced that apologies for absence had been received from the following members of Council:—Messrs. Abson, Bradley, Brittlebank, Dunstan, Gaiger, Gofton, Lawson, Sumner and Trigger.

The Secretary read the minutes of the seventy-fifth annual general meeting held on the 5th June, 1918, and they were confirmed.

#### SCRUTINEERS' REPORT.

The Secretary read the report of the Scrutineers in regard to the election of eight members of Council, certifying that the votes recorded in the voting papers for the several candidates nominated for election to Council were as follows:—

Stockman	792	Gofton	504
Bradley	751	Male	504
Lawson	539	Wharam	484
Gaiger	530	Craig	425
Willett, 407, Dunstan, 390, Locke, 342, Logan, 314, Hamilton, 287, Hill, 235, Tutt, 206, Squair, 175.			

There were 28 spoilt papers and 42 papers were received too late.

The PRESIDENT, having declared the following members duly elected to the Council, Messrs Stockman, Bradley, Lawson, Gaiger, Gofton, Male, Wharam and Craig, proposed that a hearty vote of thanks be accorded to the scrutineers for their work, which had been thoroughly and carefully done. Mr. Price seconded the motion, which was carried unanimously.

#### ANNUAL REPORT.

The Annual Report and Financial Statement was, on the motion of Mr. Price seconded by Mr. McKinna, unanimously received.

The PRESIDENT: It is usual to take the report page by page and we will follow that custom to-day. I do not think anything arises on the first page of the report, but on page 2, which deals with the meetings of the Council and the Committees, an unfortunate error has crept in with regard to the number of attendances of Mr. Lawson at the Committee meetings. He is put down as having attended only three meetings, and the number should be thirteen. It is only due to Mr. Lawson that I should make that statement. It is a very regrettable error, but I am very pleased to see that it has not affected very materially the voting. (Hear, hear). With regard to the Bye-Laws which are mentioned on page four, the members of the College will be interested to learn that they are now published separately, and any member can obtain a copy at the price of one shilling.

On the motion of Mr. West, seconded by Mr. McKinna, the Annual Report was unanimously adopted.

#### FINANCIAL STATEMENT.

The PRESIDENT: You will find the financial statement on the last two pages of the report. Has Mr. Mulvey, our worthy Treasurer, any remarks to make about it?

MR. MULVEY: I have nothing very much to say except once again to appeal to the profession to assist us with their contributions. As you will notice from the financial statement, the excess of expenditure over income for the past year was £35 8 6d. We have many calls upon us, and if the profession can see their way to help in regard to finances the Council will be deeply indebted to them.

The PRESIDENT: I can assure you, gentlemen, that until we get our Bill passed we shall be, owing to the congestion of business which is now larger than ever, very short of funds. That is a very serious matter, because you can take it from me that during the past year, going no further back than that, we could have done very many things in the interest of the profession, but we lacked the means of carrying them out. It is a deplorable position to be in, and I heartily support Mr. Mulvey's appeal to every member of the profession voluntarily to support his College by giving a fee of one guinea per annum until we get the Bill passed.

On the motion of Mr. Samson, seconded by Mr. Rowe, the financial statement was unanimously adopted.

The PRESIDENT: Gentlemen, that concludes the business of the meeting, and I thank you very heartily for your attendance to-day.

MR. REEKIE: I beg to propose a hearty vote of thanks to the President for presiding.

MR. WILLETT: I have much pleasure in seconding that.

MR. MCKINNA: I have very great pleasure in supporting it. I am glad you appreciate the work that is done by the President.

The motion was put to the meeting by Mr. Reekie and carried with acclamation.

The PRESIDENT: Gentlemen, I thank you very heartily for your kind expression of thanks. I again thank you for your attendance, which, I think, is almost a record.

The meeting then terminated.

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919:—

Anthony, W. A., Lt.-Col. R.A.V.C.	£1	1	0
Caldwell, J., Spilsby, Lincs.	1	1	0
Castle, A. F., Capt. R.A.V.C.	1	1	0

**INOCULATION OF CATTLE AGAINST REDWATER AND GALL-SICKNESS**, By LL. E. W. BEVAN, M.R.C.V.S. Fellow of the Society of Tropical Medicine and Hygiene, Government Veterinary Bacteriologist. (Issued by the Department of Agriculture, Salisbury, Rhodesia. Bulletin No. 316. [Abridged].)

The losses due to these diseases, are enormous, and may be summarised as follows:—1. Death of imported stock; shortage of bulls for improvement of local stock; loss of service to cows; unsatisfactory calves from imported stock. 2. Heavy mortality in young stock from these and associated diseases (scour, etc.). 3. Loss of growth and delayed maturity. 4. Loss of milk and dairy products.

On the basis of 10s. per head, the national loss from these causes well exceeds half a million pounds a year.

The final remedy for these difficulties will probably be found in the total eradication of the blue tick by short-interval dipping, but until this has been systematically and universally applied for some considerable time, there

will be a period of transition during which the tick and the diseases transmitted by it must persist in certain parts of the country. Moreover, it must be remembered that, when ticks are totally eradicated from an area, the live stock born and reared on it remain susceptible and contract a virulent type of the diseases if exposed on "undipped" veld. Thus it happens that those stock-owners who have for some time past consistently dipped their cattle are at present and must for some considerable time be at a disadvantage. By eliminating the ticks their cattle grow up free from and susceptible to tick-borne diseases, and if infection is delayed until they have out-grown the natural resistance associated with youth, they may suffer as severely as animals imported from tick-free countries. As the result of dipping, these men have been able to import cattle from overseas for the improvement of their stock, and, these animals have lived, they have so graded up their herds that the resistant qualities peculiar to indigenous stock have to a large extent been eliminated. It has been shewn by laboratory experiments, and proved by practical experience, that the virulence of redwater and gall-sickness becomes greatly increased by passage through cattle of improved types. In this way, if by accident infected ticks are introduced to a dipped farm and infect the improved stock on it, the virulence of the disease is of exceptional severity, and the mortality higher than in herds in which native blood predominates.

Again, should the stock reared on a dipped farm be moved to infected veld, they are likely to contract tick-borne diseases; so that the man who has succeeded, at considerable trouble and expense, in rearing valuable young animals of high quality finds to his cost that the market for such animals is limited, because of the risk of infection after purchase by stock-owners who have been less progressive in cleansing their farms.

Although dipping as a panacea for all tick-borne diseases has been preached by the Veterinary Department for many years, the transition stage through which we are now passing has been foreseen, and for the last ten years preparations have been made to cope with it. The solution of the problem has been sought in the discovery of a successful method of immunising not only imported animals, but also young stock, against tick-borne diseases, with as little damage as possible to the treated animal. After careful work and observation, it is hoped that such a method has been found.

It will be remembered that in the pre-dipping days at least 90 per cent. of all cattle imported for the improvement of our local stock succumbed. From 1909 onward attempts were made to immunise bulls introduced from overseas by inoculating them with blood containing parasites of low virulence.

[Some notes on early experiences are given.]

The qualifications which render an animal suitable for treatment are:—1. It should not exceed fifteen months of age. 2. It should not be fat, forced or pampered. 3. Its breeding should not have been such as to have weakened its constitution. 4. It should be delivered at the inoculation camp in good health, and free from ticks. 5. Females should not be pregnant, and cannot be treated except under guarantee that they are not in calf.

A great deal of distrust and misconception exists concerning the results of inoculation of imported stock, it being asserted that the operation interferes with the growth, fertility and usefulness of the animals. Much of this is not supported by fact, and after careful enquiry it has been found that, where inoculated animals have failed to give satisfaction, the fault has often been due to the carelessness and incompetence of the owner, against which no method of inoculation has yet been devised. It is most necessary that valuable animals exposed to new conditions of climate, diet and mode of

living should be given a fair chance. On circularising the owners of many of the inoculated animals, favourable reports were received from the majority, sufficiently enthusiastic to quite counter-balance the adverse criticism of the less fortunate.

The difficulties and disadvantages associated with the breeding of cattle on dipped areas can also be dealt with by inoculation of young stock, a method having been evolved dependent upon:—1. The selection of a strain of infection of low virulence. 2. The innate resistance of young cattle, and the gradual loss of such immunity. 3. The varying susceptibility of different breeds of cattle.

As has been pointed out, the virulence of a strain of redwater and gall-sickness is modified by passage through different breeds of cattle, being lowest in animals of indigenous breeds and increasing in strength by transmission through animals of exotic or imported types. By careful selection and sub-inoculations extending over a period of ten years, a strain of comparatively low virulence has been obtained, but not so mild as to be inert when applied to suitable animals. It is a matter of considerable importance that the inoculated animal shall contract the disease, inasmuch as it is only by recovery from infection that immunity is established. But since young animals possess at birth, and for some time after, according to their breeding, an appreciable degree of resistance, the inoculation must not be performed too early, that is before they become susceptible and subject to infection, or too late, when the re-action may be severe and retard their development.

[Particulars as to inoculations, and general care of the animals, with rationing for calves, concludes the bulletin].

#### REPORT OF THE GOVERNMENT VETERINARY SURGEON, CEYLON, FOR 1918.

*Assistant Veterinary Surgeons.* Mr. E. T. Hoole, G.B.V.C., Colombo; Mr. M. D. S. A. Wijayanayaka, G.B.V.C., Nuwara Eliya; Mr. G. B. de Silva, G.B.V.C., Kandy; Mr. V. A. Hoole, G.B.V.C., Ratnapura.

##### INFECTIVE DISEASES.

*Rinderpest.* There was a marked decrease during the year. Total number of cases 161, against 2076 last year. Outbreaks occurred in three Provinces, and six remained free. The total number of cases for the year outside Colombo town was 128, of which 108 died. In Colombo town 9 cases, of which 5 died. At the quarantine station 24 cases, of which 15 died.

*Foot-and-Mouth Disease.* This disease was very prevalent throughout the year, and, except the Southern, all Provinces were infected. Total number of cases 10377, against 7132 last year. As usual, the disease was of a very mild type, and spread with great rapidity. Total number of deaths 268, chiefly young sucking calves and neglected cases.

*Anthrax.* In the Provinces only 24 cases were reported. In Colombo town 3 cases, and at the quarantine station 1302 cases, amongst goats and sheep imported from South India.

*Rabies.* Seventy-four suspected cases were examined at the Bacteriological Institute, of which 23 were from Colombo town. Of these, 44 gave positive and 22 negative results. Eight were received unfit for examination. Two hundred and twenty-one persons underwent treatment at the Pasteur Institutes at Colombo and Coonoor. Thirty went to Coonoor, and 191 were treated in Colombo after the opening of the new Pasteur Institute there.

*Swine Septicæmia.* Only 30 cases were reported, all from the Western Province.

*Black Quarter.* Twenty-three cases were reported in the Southern Province, and 7 cases in Uva.

Fifteen cases of ophthalmia occurred amongst cattle in the Central Province, all recovered under treatment.

*Horses.* With the exception of one case of anthrax amongst the police horses, there was no outbreak of infectious disease during the year.

The total number of cattle and buffaloes for the whole Island is 1582060.

Compared with 1917, there has been an increase of 20 horses, and a decrease of 563 cattle, 1417 sheep and 5931 goats. Compared with 1914, the decrease in importation has been considerable—a decrease of 251 horses, 11220 cattle, 3064 sheep, and 28496 goats. Although there has been a very large decrease during the period of the war, there has been no distressing shortage of meat in the Island. The meat supply, excepting mutton, has been largely drawn from country cattle. While the stock owner benefits in pocket from the increased sale of local cattle, the complaint arises of shortage of cattle for agricultural operations.

The following figures were obtained in order to see approximately what the requirements of the Island were as regards meat supply, and the number and variety of animals slaughtered.—54896 cattle, 12091 buffaloes, and 96531 goats and sheep were slaughtered during one year (1917). Comparing these figures with the total number of animals imported in 1917, it will be seen that 61206 more cattle and 22968 more goats and sheep were slaughtered than imported; therefore, those animals must have been drawn from the live stock of the Island. The difference is even greater, as a good number of imported cattle are either for draught or cows for milking purposes.

The horses of His Excellency the Governor's Escort, the Police horses, the draught bulls of Public Works Department, Convict Establishment, and Botanic Gardens, and the Government Dairy cattle have been treated when necessary.

Thirty-eight C. M. R. horses for insurance under the Volunteer Horse Insurance Scheme have been inspected during the year.

In the early part of the year a Committee was appointed to consider the question of live stock breeding in the Island. The report will shortly be submitted to Government.

##### GOVERNMENT DAIRY.

*Manager.* Mr. P. C. J. Fernando. Foot-and-mouth disease broke out in March. Fifty-six cases occurred, and all recovered. Most of the deaths shown in the statement were due to parasitic gastritis, diarrhoea, debility, or old age. The dairy is now too cramped for land, and it is hoped to move to a new site in 1919. Land has been acquired for the purpose during the year.

Rs. 1999.50 was expended on the purchase of stock. Nineteen dairy-bred heifers were returned for calving from Ambepussa Branch Farm. Two sales were held during the year. The total amount realised was Rs. 3240.20. Thirty-one heifers and one young bull were sent to the Ambepussa Branch Farm. Had they been sold, there would have been an additional Rs. 1820 under this head. The total receipts are estimated at Rs. 47347.92, and expenditure Rs. 42347.82, leaving a balance of Rs. 5000.10. The cost of cattle foods was very high owing to war conditions.

In February the price of milk was raised from 40 to 45 cents per imperial quart, equivalent to 30 cents per bottle of 26½ ounces. The total output of milk was 23988 gallons, most of which was supplied free to Government hospitals in Colombo.

*Branch Farm, Ambepussa.* Manager. Mr. R. F. P. Jayawardena (acting).

During the year the enclosure was cleared of weeds, and buildings repaired and whitewashed. Foot-and-mouth disease broke out in August. Twenty-four of the heifers were affected, and all recovered. In February

and March there was a severe drought, and the grass was parched up, necessitating the use of paddy straw and other foods for the cattle. Twelve calves died during the year, chiefly from parasitic gastritis and diarrhoea. The total expenditure was Rs. 5624.18.

**Model Farm.** Manager. Mr. G. S. P. Dahanayaka. A few sheep are kept at this farm. In January 5 ewes and 1 ram were sold to Mr. W. A. de Vos, of Colombo, for his estate, and he reports favourably of them. In February 18 young rams were weaned out and sold to Mr. J. Mendis, who removed some of them to his estate in the Kurunegala District, and reports that they thrive well. There are several applicants for sheep, whose requests cannot be complied with at present.

In conclusion, I desire to thank the staff individually for keen work during the year. In so far as I have been able to judge by correspondence passing through the office, their efforts have also been appreciated in their districts.

G. W. STURGESS, M.R.C.V.S.,  
Colombo, Feb. 26, 1919. Government Vety. Surgeon.

#### ANNUAL ADMINISTRATION REPORT OF THE BOMBAY VETERINARY COLLEGE FOR THE YEAR 1917-18.

Mr. K. Hewlett, the Principal of the College, held charge and the staff remained unchanged throughout the year under report.

**The Students.**—There were 115 students' names on the rolls of the College at the commencement of the year. Of these eight students were eligible and appeared for the Supplementary Examination held at the end of April 1917. Of these five passed into Class B from Class A and two passed into Class C from Class B. Six students discontinued the course and one was refused permission to appear on account of his irregular attendance. The numbers were in consequence reduced to 108. The Principal at the request of the Quartermaster General in India having called for volunteers to provide veterinary staff for ships bringing mules from China to India, nine students came forward on the understanding that they would be specially examined on their return. This arrangement was sanctioned by the Director of Agriculture, and consequently the numbers who were examined at the Annual Professional Examination in November were reduced to 99, of whom 60 passed. Two of the students who went to China having returned were examined in January and passed, making a total of 62 successful candidates out of 101 examined. In the Final Year or Class C, 27 students appeared and 17 passed; in Class B 35 students presented themselves and 22 passed; in Class A 39 students presented themselves and 23 passed. Three students of Class A, six of Class B and three of Class C, although they obtained the aggregate of marks, failed to qualify in one subject and are in consequence eligible to appear for re-examination at the Supplementary Examination to be held at the end of April 1918. In addition to these there will be seven students who have returned from duty on mule ships from China.

The results of the Supplementary and Annual Examinations held in 1917-18 are:— In the Final Year 28 appeared and 17 passed, in Class B 37, and 24 passed, in Class A 44, and 28 passed.

In January 1918, 54 candidates presented themselves for admission as against 73 last year. This decrease in numbers of candidates is due to the Principal having had to discourage applicants, owing to the number in the College now being in excess of that for which teaching facilities exist (*vide* Rule 11). Of those who presented themselves, the Principal admitted 33 to Class A, 1 to Class B and 1 to Class C. The remaining candidates were refused admission on account of edu-

cational or physical unfitness. There were thus 85 admissions this year as against 41 last year and 37 in the preceding year.

There were 127 students' names on the rolls in January 1918; of these 35 were newly admitted, 45 were students promoted to a higher class, 39 were failed students and eight who had not appeared for the examination. Of the failed students seven discontinued the course and of the eight who did not appear, one left the College. There were thus 119 students' names on the College rolls at the termination of the official year as against 115 at the commencement.

**The Students' Hostel.**—The students' hostel has as usual been quite full throughout the year and accommodation therein is much sought after. All arrangements for the hostel have been carried out by Mr. Dhakmaravalla.

During the year the students have continued to avail themselves of the tennis courts. Football, hockey and cricket have also been played and several matches against other institutions have been arranged. Athletic sports were held during the year.

The health of the students has been good throughout the year.

**Riding Class, Drill, etc.**—The usual course of instruction in riding was held at the Riding School of H. E. the Governor's Body Guard at Chaupati for the final year's students and the others were put through a course of physical drill by Staff Sergeant Town, late Royal Horse Artillery, the Instructor in Shoeing.

**Clinical Instruction.**—This was carried out as usual in the Bai Sakarbai Dinshaw Petit Hospital for Animals. During the year 3,425 in-patients and 623 out-patients were treated, a total of 4,048 patients. Of these 839 were equines, 1,922 bovines and 664 others. The average daily attendance was 281.

The students have been well behaved and their attendance at lectures, demonstrations and clinical classes has been satisfactory. There have been some instances of absence from College without permission, but such have been suitably dealt with.

**The Laboratory.**—During the year under report 1,130 specimens were examined in the College Laboratory by Mr. Sowerby, the Assistant Principal and Mr. Lopez.

**Employment of Graduates.**—Of the 17 Graduates who passed out in 1917, 7 are in the service of Government or Local Bodies, 2 in the service of Native States, 1 in private practice, 2 are studying in Sanitary Surveyors Class and 5 are unemployed as yet. Of the 23 students who graduated in 1918, 21 are in the service of Government or Local Bodies, 1 is unemployed and 1 died. Of the 16 students who graduated in 1915, 12 are in the service of Government or Local Bodies and 4 are in Native State service. Thus out of a total of 56 Graduates who have passed out of the College in the last three years, 40 are in the service of Government or Local Bodies, 6 are in Native State service, 1 is in private practice, 2 are undergoing the Sanitary Surveyors Class, 6 are unemployed and 1 has died.

**The College Buildings.**—The water supply of the students' quarters was improved and special repairs to the Laboratory were carried out during the year.

**Extra Duties of the Staff.**—The Principal has this year as heretofore performed military duty throughout the year in addition to his civil duties. He holds the appointment of Deputy Assistant Director Veterinary Services (Embarkation), Bombay, with the rank of Major in the Veterinary Corps (I.D.F.). He is responsible for all veterinary work in connection with the embarkation and the Bombay Brigade and is in charge of the Embarkation Veterinary Hospital. He arranged for the supply of the veterinary personnel for a considerable number of vessels conveying remounts to the various expeditionary forces and for vessels bringing mules from Northern

China to India. The Assistant Principal, Mr. Sowerby, who holds a Commission as Major in the Bombay Garrison Artillery, was in command of a sub-district of the Bombay Coast Defences for three months and for the remainder of the year commanded his Company as usual. He assisted the Principal in his embarkation duties. Mr. Miranda, 2nd Assistant Professor, has worked in the Embarkation Veterinary Hospital and Khan Saheb Ahmed Shaikh, 1st Assistant Professor, has at times assisted him there. Mr. Lopez, the Lecturer, went in veterinary charge of a shipment of remounts to Basra. These three officers have helped the Principal and staff of the Glanders and Farcy Department in carrying out the large number of mallein tests which have been performed this year by that department and which it would have been impossible to perform without the willing assistance of these officers. Mr. Dhakmarwalla has assumed some of the ordinary routine work of the College in order to permit of these extra duties being performed by other members of the staff.

The Clerical establishment has also had to perform much extra work especially Mr. Pansare, the Head Clerk.

The Principal received instructions to convey the formal thanks of Government to Mr. Miranda for his good work in connection with the Embarkation Veterinary Hospital.

The Principal desires again to record his appreciation of the way in which all the officers of the College have performed their duties.

K. HEWLETT, I.C.V.D.,  
Principal, Bombay Veterinary College.

#### JOINT-ILL IN FOALS.

*To the Editor of the Veterinary Record.*

Sir,—I shall be much obliged if you will allow me to use your columns to intimate that this season again serum for the treatment of joint-ill in foals is being supplied gratis to members of the profession.—Yours faithfully,

J. M'FADYEAN.

Royal Veterinary College,  
Camden Town, N.W. 1., June 3.

#### ANÆSTHESIA IN ANIMALS.

From the correspondence in our daily papers and our Veterinary Journals it will be seen that there is a likelihood of an Act of Parliament compelling all operations on animals to be done under some anæsthetic.

If I might say a few words in favour of this Bill, I think as far as it goes it is a very good Bill, and in my opinion will help the profession very much; but I do think there should be no specified operations, but that all should be included.

For the last 20 years I have never done an operation except under some anæsthesia, and the operations performed have been many and various. I never had any cause for alarm or complaint, and I might say that if once a man operated under an anæsthetic he would never resort to the old method. There is the absence of increased help, and there is the comfort in controlling your patient to your requirements.

Now take the simple operation of docking. The colt or other older animal is caught, and the seat of operation put under local anæsthesia, and in a few seconds the tail can be amputated with the scalpel, and the arteries secured. There is never any evidence of pain, and the colt will stand in the same position after he is liberated. I have docked some thousands of colts of all ages, and never had to put one under restraint, beyond one man. I do all severe operations under chloroform, including parturition in ewes, and prolonged parturition in the mare.

Some weeks ago I was asked by a gentleman who is a member of the R.S.P.C.A. to castrate some colts, but I must put them under chloroform. The fee was fixed and the arrangements made. The first colt was brought out and cast on his side, and chloroform was administered; after some excitement the colt was under, and the operation performed to the owner's wish, but he thought the colt suffered a little when coming round. This I explained was the effects of chloroform and not under my control.

I then advised him to allow me to castrate the next colt under cocaine; this he consented to. The colt was cast on its side, same as the other one (which I may say is very simple and quick). After the usual antiseptic toilet the testicle was placed under cocaine, using a very long and fine needle (which is the secret of success). If the needle is plunged well into the testicle, which is very soft, the colt feels very little. After a time it comes under the anæsthetic, the scrotum is opened, the testicle is liberated, all the non-vascular parts separated, and with the castrator the operation is finished. Allow the colt to get up without any feeling of pain whatever; he walks off as if nothing had happened.

I asked the owner after if he wanted me to chloroform the third colt, but the cocaine had so pleased him, that I had to do the other the same.

At the time of writing this letter I have just operated upon a cow's teat for stricture of the duct, by opening the sinus half way up under cocaine, without the animal being held at all. The teat was laid open and re-stitched, and the cow was chewing the cud while I had the teat at my leisure.

No doubt there are others using it for their work, but if my experiences of the use of anæsthetics is a means of helping others in the cause of humanity I am satisfied.

Swanlow, Winsford.

H. BIBBEY.

#### CONFERENCE OF VETERINARY INSPECTORS.

President—JAMES MALCOLM, F.R.C.V.S.

*To the Editor of the Veterinary Record.*

Dear Sir,—Having undertaken the duties of Recording Secretary to the Conference of Veterinary Inspectors at the Royal Sanitary Institute's forthcoming Congress in Newcastle, to be held on the 1st and 2nd of August, I beg to state that Sir Stewart Stockman will give an address and demonstration on "Rabies," and the papers promised are:—

"Equine Parasitic Mange—its control and eradication," by A. Gofton, F.R.C.V.S., Chief Veterinary Inspector, Edinburgh.

"The utilization of condemned meat and other food-stuffs with waste products of slaughtering, in the manufacture of poultry, pig, and dog foods," by J. S. Lloyd, F.R.C.V.S., D.V.S.M., Chief Veterinary Inspector, and J. A. Priestly, Cleansing Superintendent, Sheffield, together with other subjects which were given in your last week's issue.

Having ascertained that many Veterinary Inspectors full-time and part-time officers—desire to be present at this important Congress, I shall be glad to receive the names of all inspectors employed by local authorities.

It is my intention to communicate with heads of departments asking them to obtain the permission of the responsible committees to allow Veterinary Officers to attend the Conference.

The Conference is held under the chairmanship of James Malcolm, F.R.C.V.S., and the Local Secretary is Thomas Parker, F.R.C.V.S., Newcastle.—I am, Sir, yours faithfully,

JAMES R. HAYHURST,  
Metropolitan Cattle Market,  
Islington, June 3, 1919. Recording Secretary.

## ON PROFESSIONAL POLITICS.

It is a long time since I have read such a sound piece of writing as that of Mr. H. C. Wilkie on this subject. I wish he would follow it up by indicating how the veterinary profession in the United Kingdom is to attain proper political influence. France has long ago recognised the value of State aid to veterinary science. The United States calls its whole hog department the *Bureau of Animal Industry*, and it sees to it that its head is a man of ability and scientific attainment in connection with animals—not a soldier, a sailor or a professional politician only. In the case of Gilruth and Reakes, is it not a fact that these men were really appointed to their positions by the Governor-General of the colonies concerned? They do not depend on the vote of the proletariat for their positions. A Governor is there with full authority and it is to the credit of these Governors that they have been very discerning men. It is not so with all our colonies. In India and South Africa a great amount of chaos prevails, and the lot of the veterinary profession there is not by any means a happy one.

It would seem that, in the United Kingdom, in order that the profession may attain the rank and position that it is entitled to, a man should be given full power to organise and administer affairs connected with veterinary science, and animal production and industry. The general lot of the veterinary profession in France is not much better than our own. The Ministry of the Interior has a pretty strong hand over it, but France has had the saving grace to associate veterinary science with the State and to aid it from the Treasury. In this way men like Chauveau have received due honour and recognition, and have been able to rise and advance. Under the present system of Government in the United Kingdom there seem to be three or four ways open to us to improve our position. Co-operation with the Universities, with agriculturists, with sympathetic M.P.s, and with the medical profession; and with all of them making certain that we keep our own hold on the right end of our stick, and preserve our needs, rights and privileges as much as possible, intact: for men acting on behalf of others are prone to go woefully astray unless frequently guided and advised. At any rate this seems to be the only way—unless some day the State gives us a surprise by recognising our worth, and putting us into undisputed possession of the positions we are entitled to, which will never be most usefully filled and properly occupied until we are there.

G. MAYALL, M.R.C.V.S.

## VETERINARY POLITICS.

Sir.—I was very interested in Mr. Wilkie's letter on the above subject which appeared in your issue of May 31st.

Mr. Wilkie's statement that the social position of the individual depends on that individual is perfectly true but I think that in grasping at the shadow he has missed the substance of the numerous letters which have appeared in the Veterinary press from time to time. I take it that the question has not been one so much of the individual as of the profession in the abstract.

There are numerous instances in England, without wandering far afield, of individuals who have held very high offices under the state and highly esteemed withal. One need only mention such men as Sir George Brown, Director of the Veterinary department of the Privy Council, of whom the late Duke of Richmond and Gordon placed on record that he was the most able organizer and administrator he had encountered—Sir Stewart Stockman, Edward Nettleship who, although distinguished in ophthalmology, never forgot up to the day of

his death that he was a veterinary surgeon—Sir John M'Fadyean who was on the Royal Commission of Tuberculosis—Dr. O. C. Bradley professor of comparative anatomy in the University of Edinburgh—Griffiths Evans who discovered the trypanosomes. There are many others one may mention did space permit.

We have also received recognition from the Board of Agriculture as evidenced by the trust placed in us in the present outbreak of Rabies. And this is all the more remarkable after the experience of the Veterinary Department of the Privy Council when during the outbreak of pleuro-pneumonia upon investigating cases which were reported as post-mortemed and found affected by certain members of our profession, it was found on exhuming the carcasses that the skins had not even been cut.

The Army has also recognised us and this prominence has been far above that given to the veterinary profession by any other army.

But it must indeed be a thick skinned and unobservant man who can say that the profession is not held in disdain and from some points of view justly so. There must, of course, be some reason for this and by studying the question it becomes apparent that the status of any profession depends on the percentage of eminent or respectable members as compared to the "blacklegs," and the greater the former the higher will be that status.

The other professions are only too willing to receive us with open arms and I have found that the medicos have always regarded veterinarians as their equals in learning and apparently delight in engaging us in the most highly scientific discussions in order to derive benefit from our knowledge, and their deference to us as a profession both in civil and military life has struck me as highly complimentary.

Like all other questions there are two sides to this one and on turning our attention to the "horsey" and "doggy" people, to say nothing of the truly ignorant, we find the exact reverse—the majority entertain the greatest contempt for us and often non-plus the youthful practitioner by openly telling him so. Several instances of this may be mentioned. Remount officers, usually "horsey" civilians, seldom or never consult their veterinary officer and I have listened with amusement to these types holding forth on the treatment of the various species which they may favour.

In the last issue of "Fur and Feather" there was an article on the "Neutering of cats" in which a "catty" lady gives forth her opinion to the world on the best period for the operation. Is it owing to the fact that she found that a great number of the cats of both sexes which she had had operated upon died as a result of the operation?

Such a state of affairs will not be altered by individual endeavour, propaganda nor political influence so long as we have practitioners who make use of "touts" or themselves "tout" for the R.S.P.C.A., actually give certificates without making an examination, cut prices and squabble with each other in and out of the police court, and are not above belittling, in the eyes of the public, their fellow practitioners, who are in many cases far more efficient than themselves, in the too often vain endeavour to promote their own advancement.

In *The Daily Telegraph* a few years ago there appeared an article from the pen of Sir E. Ray Lankester, in which he stated that veterinary surgeons held medical science in the hollow of their hands. What have we done to justify this chivalrous statement? We have adopted the attitude of complete isolation, instead of working in concord with human medical men, to whom our special opportunities and qualifications are almost indispensable in building up the edifice of pathological science and public hygiene. Is it because that we are conscious of our own inferiority in learning? We have persistently held aloof and so to speak in a water-tight compartment.

Contrary to Mr. Wilkie's statement, opportunities of wider study were afforded us by the University of Liverpool which was opposed by the majority of the profession, much to its detriment.

In spite of this veterinary surgeons may take courses at any of the Universities, certain of the medical schools and may also study immunity under Sir Almroth Wright. There is also the Lister Institute and the Brown Institution in both of which research work may be carried out, and these institutions are always ready and willing to render all possible assistance to veterinary practitioners when consulted.

Further, we can have access to the unsurpassable museum and library of the Royal College of Surgeons. But how many take advantage of such opportunities? And do we, on our part, offer such opportunities to the members of the sister profession? Are our libraries and museums worthy of a profession which desires to be looked up to as a learned one? I was surprised when collecting some information on diseases of the horse's teeth to find such a priceless collection of specimens both of human and veterinary, not to mention of wild animals, as was shown to me in the Royal College of Surgeons. There was no water-tight compartment study but embraced both branches of the profession, and one cannot help thinking that had we contributed to research on our patients and combined with the medicos, one would have been saved the thought that the medicals had trespassed on our preserves and had gained the credit.

In our profession this water-tight attitude is carried still further, the horse-doctor looks down on the cow-doctor, who in turn regards with contumely the dog and cat man, and contempt regurgitates the reverse way so that each branch despises the other. Again, the "rule of thumb" practitioner who prides himself on being "practical" despises his more scientific and perhaps more skilled confrere.

When we shall have eliminated these so-called "practical" men and replaced them by more thoroughly educated and better skilled clinicians, and developed sufficient *esprit de corps* in that those at the top will encourage those below to climb instead of neglecting or actually pushing them down, we shall see the veterinary profession greatly advanced in public opinion and with very little more assistance than afforded by a devoted and far-seeing Council.

G. O. RUSHIE GREY.

#### ROYAL ARMY VETERINARY CORPS REWARDS, HONOURS AND DECORATIONS FOR WAR SERVICE.

"To the Editor of *The Veterinary Record*."

Dear Sir,—May I suggest that there be published a list of those veterinary officers who have received the above, in a form similar to that published in the *London Gazette* giving with each name a brief account of the service of each officer with details of the particular act or acts for which the award has been made.

Much has been made of the fact that decorations which are looked upon as solely conferred for acts of gallantry to actual fighting men, have been awarded to those practically employed as non-combatants and on the lines of communication.

By the publication of such a list the profession could better judge of the merits or demerits of individual cases.

Separate lists should be prepared for each theatre of war and under the heading of Regular, Territorial, Special Reserve and Temporary.

This list should be published as a complete supplement to the regular issue of *The Record*.—Yours truly,

"DEMOBILIZED."

#### ARMY VETERINARY SERVICE

The King held an investiture in the quadrangle of Buckingham Palace, on May 22 at 11 o'clock.

The following Officers were severally introduced into the presence of The King, when His Majesty invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted:—

THE MOST HONOURABLE ORDER OF THE BATH  
Companions—Military Division.

\* \* \* \* \*  
Lieut.-Col. ARTHUR OLVER.

THE MOST EXCELLENT ORDER OF THE BRITISH EMPIRE.  
Officers—Military Division.

\* \* \* \* \*  
Major PERCY DAYER-SMITH, Capt. DICKINSON STARKEY,  
R.A.V.C.; Major SAMUEL RICHARDS, Capt. WILLIAM  
ROBERTSON, Canadian Army Veterinary Corps.

\* \* \* \* \*  
Members—Military Division.

\* \* \* \* \*  
Capt. FREDERICK SHEEDY, East African Vety. Corps.

\* \* \* \* \*  
THE MILITARY CROSS.

\* \* \* \* \*  
Capt. SYDNEY SLOCOCK.

\* \* \* \* \*  
Capt. CHARLES MACHONACHIE (May 29).

\* \* \* \* \*  
THE DISTINGUISHED SERVICE ORDER.

\* \* \* \* \*  
Lieut.-Col. HENRY AXE (May 31).

May 23.

His Majesty the King has been graciously pleased to approve of the following immediate awards for conspicuous gallantry and devotion to duty in North Russia, conferred by Major-Gen. C. C. M. Maynard, C.B., C.M.G., D.S.O., in pursuance of the powers vested in him by His Majesty.

\* \* \* \* \*  
AWARDED THE DISTINGUISHED CONDUCT MEDAL.

\* \* \* \* \*  
34728 Vety. Sergt. F. J. FRAPE, R.A.V.C., attd. Can. Field Artillery.

For conspicuous gallantry in action. He played a decisive part in the first phase of the attack. Gathering together a number of drivers, he took charge and fought stubbornly, falling back slowly in face of superior numbers. He himself accounted for several of the enemy, this work contributing largely to the saving of the situation. By this check on the enemy time was given for preparation of the defence of the guns.

Died 17th May, 1919, Aged 63.

#### TICK ERADICATION IN U.S.A.

The following is from an address by J. R. Mohler, Chief of the Bureau of Animal Industry at conference of B. A. I. Employees, New Orleans, in February.

"Since coming into this gathering of those so vitally interested in tick eradication, my mind has reverted to a somewhat similar but decidedly smaller meeting which was held at Richmond, Va., in the fall of 1905. The occasion was the annual convention of the Southern Commissioners of Agriculture, and the audience consisted of less than two score men. I was afforded the privilege of choosing for my topic whatever subject I considered the chief prerequisite in tick eradication and I selected the title 'The Education of the Owner of Ticky Cattle.' In those days men like one of the late Senators of South Carolina thought tick eradication

was ridiculous, and on one occasion while visiting Clemson College he said his grandfather's cattle had ticks, his father's cattle had ticks, and his own cattle had ticks, and if they were harmful he would have found it out ere this. However, long before this able man died he was an ardent tick eradicator, and the State which so signally honored him was taken out of Federal quarantine, as you all know, on the first of last December.

It is a long, tortuous trail from those early days to the present and it has been one of constant effort on all our parts to educate, re-educate, and then educate once more.

Tick eradication in the past two years has made a notable record. In 1917 the 70,754 square miles released from Federal quarantine far surpassed the record of any previous year. Again, in 1918, the release of 79,217 square miles eclipsed all previous accomplishments. These figures would command attention at any time. But they become truly remarkable when we remember that in 1917 and 1918 the United States was at war, and every energy of the American people was bent toward the one aim of whipping the Hun. Many of our Bureau men joined the colors, tens of thousands of men left the farms of the South for the army, it was difficult to ship supplies into this section because of the demands of the cantonments, everything was submerged beneath the one dominating purpose. But, despite all that, tick eradication in 1917 broke all records, and in 1918 we found that 1917 was nearly 9,000 square miles too slow.

Much of the credit for these record-breaking accomplishments belongs to you, the representatives of the Federal Government in the fight against the tick. But we should be vain and foolish if we tried to appropriate all, or even most, of the credit. We must give full recognition, in the first place, to the cooperative work of the State governments and State agricultural colleges, and the county governments. We must acknowledge the aid of such organisations as the Southern Cattle-men's Association, the Texas Cattle Raisers' Association, the Florida Tick Eradication Committee, the Southern Settlement and Development organisation the Georgia Land Owners' Association, and the Southern Pine Association. We must recognize the consistent and clear-sighted support of the daily and weekly newspaper and the agriculture and live stock journals of the South, without whose aid we might still be battling with prejudice everywhere. And we must give due credit to the associations of the bankers and other business men who have led their communities to a realisation of the benefits of tick eradication.

More than that, we must, everyone, take off our hats to the farmers, live stock raisers, and other people, in general of the South. We must remember that while these people were helping tick eradication, they were not only buying Liberty Bonds, subscribing to Red Cross and other organisations, and sending their sons to war, but were accomplishing notable things in raising the food crops that were regarded as essential to a strong America. When the slogan "The South Must Feed Itself," was sounded the farmers of the South answered. Before the war the South imported annually about \$600,000,000 worth of corn, hay, grains, mixed feed, flour, meat and meat products, dairy products, poultry and poultry products, and canned goods. There has been a great change. In 1918 the fifteen Southern States, including all the tick-infested States, produced 141,787,000 bushels more corn than they harvested in 1909. The eleven States comprising the cotton belt produced 135 per cent more wheat in 1918 than in 1909. These same States during the same period increased their oat crop 133 per cent; their hay yield, 128 per cent; Irish potatoes, 117 per cent; and sweet potatoes, 67 per cent. The same tendency is shown in live stock production. As an instance, in 1914 Mississippi marketed only 88,229

fat cattle, while in 1916 it shipped 156,237 animals to St. Louis market, an increase of 181 per cent.

When we look back over what has been done, and consider that we are sure of the increasingly strong support of the Southern people who have done such great things, there is no reason whatever to fear that tick eradication will not win the most complete success, and that through tick eradication the South will become the live stock section that it should be by reason of its climate and other natural advantages.

The total number of cattle dipped in the South Texas counties during January, 1918, was 1,033 herds, comprising 43,213 cattle. A total of 17,983 cattle, or 286 herds underwent systematic dipping, while the remainder, or 747 herds, including 25,330 cattle received preliminary dipping.—*Journ. American V.M.A.*

#### Joint-Ill Investigation.

A meeting of the council of the Clydesdale Horse Society was held in the registered office, Glasgow, Mr. James Kilpatrick, in the chair. On the motion of Mr. George A. Ferguson, the convener, the minute of this committee was adopted. Payments were authorised, amounting to £75 or thereby, in connection with this work. Serum is now being distributed, and applications for supplies from responsible veterinary surgeons should be made to Mr. Wm. Brown, M.R.C.V.S., Marischal College, Aberdeen, for the north and north-eastern districts; Prof. Charnock Bradely, M.R.C.V.S., Royal (Dick) Veterinary College, Edinburgh, for the eastern districts; and Mr. T. B. Hamilton, M.R.C.V.S., Pollokshaws Road, Glasgow, for the western and south-western districts.

#### Suspected Pigs.—Heavy Fine.

At Colchester before Mr. T. Hetherington (in the chair), Col. Tyler, Major Tufnell, and Mr. C. E. Benham, Frank Bensley, butcher's manager and dealer, Middleboro', pleaded not guilty to exposing six diseased or suspected pigs in the market.

The Town Clerk (Mr. H. C. Wanklyn) briefly outlined the Swine Fever Order, and said on the 29th March Mr. Tayler, the veterinary surgeon appointed under the Acts, saw six pigs in the market, each with symptoms of swine fever. Mr. Tayler gave instructions to Inspector Cannell to have them removed. The Inspector made inquiries, and went to the defendant's premises in Middleboro'. He admitted the pigs were his, but said he thought they were all right. The pigs were then removed, and the defendant placed them in a sty or box, in which were others, two of which were healthy, at the back of the premises.

Mr. Rowland Tayler, M.R.C.V.S., said he killed one of the pigs, made a post-mortem, and found it to be suffering from swine fever, and that had been confirmed by the Board of Agriculture.

Inspector Cannell said defendant told him he purchased them, with others, at Sexton's and he kept them 28 days before putting them on the market. Defendant sold two of the pigs to Mr. Doe, and both died.

Defendant said the pigs always appeared to be all right or he would not have put them into the market.—Cross-examined: He admitted that they looked a bit queer when he bought them, but he did not think it was swine fever. He kept three pigs for his boy, and they were quite healthy.

A fine of £15, with £1 11s. 6d. costs, was imposed.—*East Anglian Daily Times.*

VOL. XXXI.

## THE N.A.V.I.

The National Association of Veterinary Inspectors, which was formed not long before the war but lapsed into inactivity after the outbreak, is now in process of resuscitation. A meeting of the Council was held last month to decide upon the best method of accomplishing this, and especially of inducing all veterinary inspectors, both whole and part-time, to join the Association. Numerical strength is the most essential factor towards the attainment of the objects of the Association.

Every veterinary inspector may see the advisability of joining the Association. The membership subscription of five shillings per annum is quite nominal: and the advantages of such a society are self-evident. Many matters connected with veterinary inspection could be far better dealt with by a strong association of veterinary inspectors than by any other body. Our correspondence column supplied a good case in point some two months ago, when the President of the Western Counties V.M.A. wrote asking for information regarding County Council fees and mileage in other districts than his own. The Association, had it then been in that full working order to which it is hoped to bring it, could quickly have supplied this information, and also given invaluable aid in furthering the object with which the question was put—the levelling up of County Council fees. And this is only one of many similar aims which a strong association would help to attain. We are facing considerable changes in our civil life, and the veterinary public service must share in the process. A speedy and thorough re-casting of the whole conditions of veterinary inspection has never been so probable as it is now; and hence the necessity for a strong National Association to secure that it is done on good lines.

Their executive have done well in fixing the Annual Meeting at Newcastle, the day before the conference of the Veterinary Section of the Sanitary Institute of that city. Many veterinary inspectors are likely to be attracted to the latter meeting by the prospect of Sir Stewart Stockman's address and demonstration on rabies; and those who came a day earlier would strengthen the hands of the N.A.V.I. Most men could spare the extra day for such an object, and all can spare the trifling subscription for the all-important purpose of swelling the membership. The Association may prove the chief factor in bringing the veterinary civil service of the country to the position it should hold, but only upon condition of a strong membership. We have never had a better opportunity of living up to our motto of *Vis unita fortior*.

## BOVINE COCCIDIOSIS OR COCCIDIAN DYSENTERY.

A. Railliet, in the *Recueil de Médecine Vétérinaire* of the present year, gives an account of this disease, including some details of its history and distribution. The earliest ideas of it are due to Pröger, a veterinarian of the Berne district, who reported observations made upon calves which died in two or three weeks with symptoms and lesions of acute enteritis. Pieces of intestine were sent to Zürn, who found a parasite which he regarded as a gregarine. Afterwards Railliet and Lucet, Zschokke, and others, considered it a coccidium, which, on account of its specificity for cattle, was called the *Coccidium bovis*. To-day it is also known by the name of *Eimeria Zürni* (Galli-Vallerio).

Bovine intestinal coccidiosis is especially diffused in Switzerland. It has been reported in France and in Germany. In Italy cases of it have often been seen in Piedmont, in Emilia, and in Venetia. Gair has observed it in Scotland. In Africa it was observed in the Transvaal by Thielér, in British East Africa by Montgomery, and in Tunis by Ducloux. In Australia it was observed by Clelan, and in North America by Schulz, and by Th. Smith.

The disease appears in animals varying in age from six months to two years, but is particularly grave between ten and eighteen months. Smith has seen it even in sucking calves. It presents enzootic characters in young animals, and sporadic in old ones.

The affection begins with diarrhoea, or at other times with the emission of blood-clots without any other symptom. Later, the diarrhoea changes to dysentery; and in the fæces, which are rich in mucus, the blood continually becomes more abundant. There is fever, and irregularity or cessation of rumination. The animals visibly become emaciated, and show weakness of the hind quarters and a notable difficulty in rising.

The disease is almost always grave or mortal in young animals. In general, the prognosis should be guarded when disturbances of rumination appear very early. The mortality oscillates between 5% and 13%.

At first the lesions are limited to the rectum, the mucous membrane of which is thickened, hyperæmic, and sprinkled all over with hæmorrhagic points. Later (on the fifth or sixth day of the illness) the colon and cæcum are also involved; and, in cases in which the animal dies after eight or ten days from the initiation of the process, all the intestine appears involved.

The disease is transmitted by means of water. All veterinarians are agreed in recognising that

marshy waters and the grass of humid meadows are particularly dangerous. The disease appears in June or July, twenty or thirty days after the animals are taken to the pasture. It lasts all the summer, and declines towards the month of November.

As regards prophylaxy, one of the first rules to be followed is that of keeping the animals away from suspected or humid meadows. Good drinking water and dry food should be given. Affected animals must be separated, and it is necessary to remember that some animals which appear healthy may be the bearers of coccidia.

This necessitates a systematic examination of the excrements of all the cattle, and the removal of those in whose faeces parasites are found. If the disease prevails in a cow-shed, in addition to the above measures, disinfection of the ground, frequent changing of the litter, and the destruction or disinfection of faecal material are also indicated.

As treatment, Smith advises the following mixture—powder of Acacia catechu 8 grammes, powdered asafoetida 4 grammes, tincture of opium 8 grammes, creosote 4 grammes, and water 850 grammes. This makes one dose, which is given in gruel, and repeated twice daily.—(*La Clinica Veterinaria*.)

W. R. C.

#### COCCIDIOSIS BOVINE.

In 1878 Zurn noted the presence of coccidia in the intestinal mucous membrane of a calf, which had died of acute enteritis. The same year Rivolta considered the coccidium of the rabbit as distinct from that of the ox. Since then the malady has been recognised in all European countries, and in South and West Africa, and elsewhere. To it has been applied a variety of nomenclature—hæmorrhagic enteritis, red diarrhoea, coccidian diarrhoea, coccidian enteritis, dysentery, etc. Since then zoologists are not entirely agreed as to whether the parasite as affects both animals is one and the same.

The author has had in 1917 an opportunity to undertake the study of this affection in bovines, he mentions the frequency of spherical forms, different from ovoid forms found in the rabbit. Pathologically the coccidium of the ox shows no tendency to invade the liver and provoke dysentery. That of the rabbit invades the liver and provokes only diarrhoea. Coccidiosis of the rabbit is widely spread in the farms and breeding grounds. That of the ox is confined to certain regions. Guillebeau has not been able to convey the diseases from cattle to rabbits. The author in recent attempts has also been unsuccessful.

From the point of view of prophylaxis and therapeutics, it is very difficult to act against the coccidium. Numerous agents are ineffective, namely creolin, lysol, resorcin, hyposulphate of soda, tannin, nitrate of silver, sulphate of iron, alum. Atoxyl with sodium chloride should have marked effects. Chlor. of emetine and salvarsan will be tried.

The problem of disinfection of manure is very difficult.

The author notes the following conclusions:—Bovine coccidiosis is due to a special species. It is disseminated in stables, byres, and fields by affected animals. Unless disinfected properly these places retain the infecting agent.

As good prophylaxis the following precautions are essential:—

- (a) Isolation of the sick, and treatment by an agent capable of sterilising the parasite..
- (b) Disinfection of manure by sulphuric acid.
- (c) Drainage of pasture, and provision of clean drinking water.—*Archives Vet. Suisse*.

#### RED DIARRHŒA OF BOVINES

##### (INTESTINAL COCCIDIOSIS IN VENETIA).

M. Cremona, who is assistant at the clinic of the Veterinary College of Turin, reports that Bovine coccidiosis is more frequent here in Italy than is generally known. He has had opportunities to study it clinically, and to be able to diagnose it microscopically. *Coccidium bovis* develops more particularly in animals of twelve to eighteen months old pastured on the low marshes of Venetia. He has, however, noted it also in one animal of five years and in another of only six months.

In some cases the course of the disease is extremely rapid, and death may occur in four or five days, which is preceded by a rapid emaciation, attacks of convulsions and the passage continuous of blood clots.

The treatment recommended by San Lorenzo, mainly, thymol in doses of 10 to 15 grammes, gave some cures in four to five days.—*Il Nuovo Ercolani*.

L. J. K.

#### VETERINARY POLITICS.

In reply to Mr. Mayall, I should suggest that the best method we can adopt in order to acquire proper political influence is to assert our right, our full capacity, and our fixed intention to be the sole authorities on all matters connected with animal diseases, whether they may influence the public health or not; and to that end to instruct the public (and therefore all governing bodies) by means of constant propaganda not only that the veterinary profession is the sole competent body to deal with such matters, but also that we have at least as much administrative ability as any other section of the community, and can conveniently dispense with outside assistance in that respect.

Before such convictions can be impressed upon the public mind, I believe a great deal of hard work would be necessary and a considerable amount of time required. I think it could only be done by means of *continual* propaganda, but as all other professions have been so ably advertising themselves in this way—at least ever since I can remember anything—we have plenty of examples at hand of the art of keeping before the public.

I believe most of the matters referred to by Mr. McIntosh in his paper, which originated this controversy, and those commented on by many writers since, are due to apathy on the part of the veterinary profession and ignorance on the part of the public.

Professor Macqueen said, some time ago, that the profession must first induce its members to take an interest in itself. That remark cannot be too often repeated, and I believe that a great deal of our constitutional apathy is due to a want of appreciation of the fact that the progress of the individual is dependant on the progress of the community to which he belongs, and that one cannot dissociate the welfare of the one from that of the other in the case of the relationship of a man to his profession.

We are, as a profession, no longer in our childhood. We have grown up, and I, for one, am not ashamed of our manhood, but we can never become really strong without more unity of purpose. Our purpose in this connection should be the full exposition and continual driving home of actual truths about all matters for which we are, or should be responsible.

For example, we know very well that a large percentage of the meat killed in this country is submitted to no proper examination whatever; also that the amount of efficient dairy inspection which takes place in the United Kingdom is just sufficient to show what a complete sham it is, and how hypocritical is any suggestion that the State is making a serious effort at all to safeguard the public health in these directions.

This condition of affairs is due to general and very complete ignorance. For that ignorance we are to blame, as we are the proper persons to instruct; and for the shams we are largely responsible because we have not had the strength of character to compel the authorities to allow us to do what we very well know is our duty to the public.

I do not hold the view that the State will ever take the initiative in reforming matters which concern the veterinary profession, since my belief is that the State follows some distance behind public opinion, and never does anything which it is not obviously obliged to do.

The State is like a very unintelligent child which needs to have its lessons labouriously drummed into it before it can learn anything.

Other professions have gone through the hard work of forcing information about their capacities and their rights on the State, and it is high time the veterinary profession began to give some instruction in its own interests.

Mr. Grey raises some points regarding which I am not quite in accord. He does not consider political influence by means of propaganda will effect any alteration in the present state of affairs so long as certain disreputable practices are in vogue with a certain class of member.

I do not hold this opinion, for we cannot alter human nature, and we are not the profession responsible for either the growth or decay of morality. All we can do as a preventative measure is to remove temptation from those who are weak, by the improvement of the general conditions of life. That general prosperity enormously decreases crime is demonstrated in New Zealand, where the abolition of real poverty has been followed by the nearly total disappearance of serious offences.

Our only curative measure is removal from the Register, and if we may judge of our moral status from that record I think it will be found that convictions for disgraceful conduct are far more numerous in both the legal and medical profession than in our own.

It is true, our occupation does not present either the opportunity or the temptation to such crimes as embezzlement, fraud, illegal operations, etc. The smaller mean tricks to which Mr. Grey especially alludes, I can see only as evidence of the struggle for existence by those handicapped with weak and selfish natures; and that struggle it is the duty of the profession to render less acute, while punishing the offences.

I do not, however, agree with Mr. Grey that the profession is treated contemptuously. I should rather say it is treated by the general public with an indifference due to ignorance—the phenomenon is passive, not active.

I think Mr. Grey's remarks about our museums and libraries a very useful subject into which to let the daylight of free discussion. I very fully agree with him that our museums and libraries are utterly unworthy of a learned profession.

Had the veterinary profession had anything like a properly constituted museum at all in this country, the four years of war alone should have provided more pathological specimens and surgical and pathological drawings than we have actually collected in considerably over a century.

HENRY C. WILKIE, F.R.C.V.S.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919:—

Appleton, A. F., Col., Bromley, Kent	£1	1	0
Brown, J., Stirling	1	1	0
Buxton, J., Highgate	1	1	0
Goodall, T. B., Christchurch, Hants	1	1	0
Hayes, J. W., Capt. R.A.V.C.	1	1	0
Hogben, H. P., Folkestone	1	1	0
Knowles, R. W., Wisbech, Cambs.	1	1	0
MacCormack, H. A., Tufnell Park	1	1	0
McPherson, W., Huntly, Aberdeenshire	1	1	0
Moss, M., Sevenoaks	1	1	0
Sewell, W., jun., Capt. R.A.V.C.	1	1	0
Watchorn, F. W., Newtown, Mon.	1	1	0
Previously acknowledged	832	0	10

June 11.

£844 12 10

#### THANKS TO ELECTORS.

"To the Editor of The Veterinary Record."

Dear Sir,—Will you kindly allow me through the medium of the *Veterinary Record* to express my thanks to those Fellows and Members of the Royal College of Veterinary Surgeons who, by their votes, have secured my election as a Member of Council. I appreciate very highly the honour conferred upon me, and I shall endeavour to merit the confidence of the Profession.

I am, yours faithfully,

R.V.C.I., Ballsbridge,  
Dublin, June 10.

J. F. CRAIG.

Dear Sir,—May I be allowed through the medium of your paper to thank all those members who kindly gave me their vote at the Election of Council.

It was a hopeful sign to see so many new candidates come forward willing to give their time and labours on behalf of their fellow members, but when one considers that barely a third of the profession took the trouble to vote, it shows what little interest is taken in the deliberations of our governing body by the majority.

As an unsuccessful candidate I would earnestly urge that every member should give "Our Council" every support possible both morally and financially during the critical times the profession is now passing through.

6 Harley Place,  
Harley Street, N.W.  
June 6th.

Yours truly,  
J. WILLETT.

Dear Sir,—Please allow me to thank those gentlemen who recorded their votes in my favour.—Yours faithfully,  
55 Southgate Street,  
Winchester, June 8.

JOHN B. TUTT.

To the one hundred and seventy-five veterinary surgeons who recorded their votes in my favour at the recent election I beg to tender my sincere thanks.

I was entered in the fray almost before I knew myself, and my first impulse was to have my name struck out. Had I done that it would have been better, as the 175 votes would have made all the difference to some of those general practitioners who failed.—Yours faithfully,

The Gables, Reigate,  
Surrey, June 8.

CHAS. A. SQUAIR.

#### ANÆSTHESIA IN ANIMALS.

Sir,—Mr. Bibbey's article on the above is very interesting, I think a few working details would be of further interest. For instance in the case say of a Clydesdale mare foaling, who attends to the administration of the anæsthetic while Mr. Bibbey is operating, supposing the operation lasts two hours? The operator as we all know would not be in a fit state to run round to the head of the mare and to administer so much A.C.E. then return to his work behind. It looks simple and easy on paper, but what about practice? Mr. B. may oblige with a few details.

Kirkby Stephen.

R. M. MALLOCH, M.R.C.V.S.

As one of the old school, I cannot boast of being an adept in the use of anæsthetics, and was therefore much interested in Mr. H. Bibbey's article in last week's *Record*, and if not asking too much I would like Mr. Bibbey's reply to the following.

1st: What time it takes, from the moment that a yearling colt is placed in front of the operator for castration, to rope, chloroform, disinfect, operate, and the effects of the chloroform to pass off before the colt can be left with confidence? I have seen a very uncomfortable effect following chloroform on some animals. The owner of the colt also, as stated by Mr. Bibbey, "thought the colt suffered when coming round!"

2nd: I may be wrong, but it seems to me that the sharp pain induced by the plunging of a long needle into such sensitive organs as the testicles, (as both have to be pierced) will be equal, if not more acute than the dull sensation caused by the pressure of the clam on the cord.

3rd: The case of difficult parturition in a big Clydesdale mare, when only the tail and the points of the buttocks (ischii) are presented, and the hocks out of reach; would Mr. Bibbey keep the mare under the in-

fluence of the chloroform whilst he removed one or both hind legs by cutting from the stifle cross and through the hip joint, and remove the limbs by pulling the head of the femur first; eviscerate the foetus, break through the obturator foramina on each side of the symphysis, and pass a stout rope in the form of a loop, through the opening to pull the remains of the foetus away? Does any one know an easier and better way to deal with this presentation? for it is hard work!

4th: Docking with one man and without restraint. This, to me, is marvellous. For a young colt to allow anyone to stick a sharp needle through skin, muscle and bones of the tail without restraint, and the colt not show his heels! How is it done?

I would not on any account like to see or hear of any dumb animal being made to suffer unnecessary pain when undergoing an operation; yet at the same time I think there is far too much faddy, sentimental preaching about veterinary work generally. How will the new Act deal with a sheep farm with 500 to 600 ram-lambs to castrate and dock at the same time? Will they have to be chloroformed.

Aspatia.

H. THOMPSON, M.R.C.V.S.

#### QUACK BREEDING.

While we have to deplore the manufacture of many quacks, through the instruction given to men of the R.A.V.C.—a very one sided and inadequate equipment for any civil work—we should certainly protest against the official insult to the profession contained in the "Officers Guide to Civil Careers" page 49. "Veterinary Surgery. Though a license to practise as a veterinary surgeon is not essential, the diploma of the Royal College is of the greatest value to those who wish to found a successful business."

I understand that a protest has been made by our much abused Council, and in future editions this stupid sentence will be deleted.

"DIOGENES."

#### RECONSTRUCTION.

Those correspondents who have been writing about the status of the profession may well turn to the "Officers' Guide to Civil Careers," if they would get at the official estimate of our dignity and worth.

At page 49, "Veterinary," it is stated that "though a license to practice as a veterinary surgeon is not essential, the diploma of the Royal College of Veterinary Surgeons is of the greatest value to those who wish to found a successful business."

We are singled out for this insult, while intending candidates may apply for as much as £220 per annum to assist them in obtaining a diploma which is not necessary.

With R.A.V.C. non-coms. advertising themselves on the strength of having taken temperatures and done routine dressings on the one hand, and the official encouragement of Quackery on the other, there is but a poor look out for any but the officially placed or well established among our members.

"OLD OBADIAH."

#### ON PROFESSIONAL HAIR SPLITTING.

There is a certain class of writer which reminds one of a certain class of speculator in that he not infrequently tries to hedge. But hedging, and especially literary hedging, is a very subtle art. It should not be attempted by the unwary, or by the egotist, who in his efforts to prove a goose to be a swan must needs return to the original idea in all its crudity, and keep grinding away

at it with the persistence of a pre-war Italian on a street organ. Thus, on reading an amplified attempt to draw a distinction between the social and political status of the profession one seemed to catch the following refrain:—

The voice that breathed o'er England,  
From Propaganda bowers,  
Said Veterinarius must be praised,  
He is a friend of ours.

I have just remarked that hedging is a ticklish business. It cannot be accomplished by backing the same horse after a change of its name. Neither can the literary hedger get out of a doubtful investment by begging the question. Here it seems pertinent to propound a riddle: If the veterinary profession enjoys equal social advantages with all other vocations how does it happen that "Our lack of political influence is the foundation of every important disadvantage, . . . keeps down our fees, . . . helps quackery, and allows other professions and laymen to butt into our special provinces to our manifest disadvantage?" The answer is: Because the veterinary calling is treated with disdain, and that lack of political influence is merely another name for lack of social influence. In this connection one is forcibly reminded of the Baths of Leuk, where every mud-bather has, if he so desires, his own private floating table, with writing materials and a cup of coffee. But the mud is everywhere all the same. Metaphorically the mud which surrounds the profession is the same whether one calls it social or political mud. And even the optimists who write in the reflected glory of highly polished tables do not seem very hopeful that propaganda waters will remove the stains this side of the millennium in the United Kingdom. One, in those circumstances, fails to gather what good can accrue from the formation of mutual admiration societies. The great B. P. may be an ass, but it is rather cute at nosing out dope in literary provender, and may say with Hamlet, "Somewhat too much of this," when it comes across that systematised form of propaganda which the mutual admirationists had selected for its perennial consumption.

"WATCHMAN."

#### NATIONAL ASSOCIATION OF VETERINARY INSPECTORS.

Sir,—Will you be so kind as to allow me to announce that gentlemen wishing to join the above Association should send in their names to me, but *should not* enclose their subscription, which will be collected by the Hon. Treasurer, in due course. Applications for membership should be received not later than July 20th, in order that they may be put forward for election at the next Council meeting.—Yours faithfully,

London Road,  
Kettering. June 9.

TREVOR SPENCER.

#### ROYAL ARMY VETERINARY CORPS COMFORTS FUND.

The annual general meeting of the Royal Army Veterinary Corps Comforts Fund was held at the Royal College of Veterinary Surgeons, 10, Red Lion Square, W.C., on Wednesday afternoon June 4th 1919, Mr. Frank W. Garnett, C.B.E., President of the Royal College of Veterinary Surgeons, occupying the chair. The following were present:—Mrs. Blenkinsop (Hon. Secretary), Mrs. Martin (Hon. Treasurer), Mrs. Moore, Mrs. Cochrane, Mrs. Wadley, Mrs. Nichol, Mrs. Todd; Colonel Martin, Colonel Stordy, Mr. T. Salusbury Price, Mr. J. Willett and Mr. A. W. Mason.

At the opening of the meeting, Mrs. Blenkinsop (Hon. Secretary) read the following Annual Report:—

Mr. Chairman, Ladies and Gentlemen:—Before reading my very short report upon the work of the Royal Army Veterinary Corps Comforts Fund for the past year, I am asked to express the regret of several members of the Committee that they are unable, for various reasons, to be present to-day—Mrs. Thomson, Mrs. Garnett, Mrs. Kay Lees, Mrs. Dunlop Smith, Mrs. Mosley, and Mrs. McKenzie. I'm afraid we have temporarily lost, or shall I say "misplaced" Mrs. MacGowan, as two letters have been despatched to her without result. We shall hope to find her later! We will now get to the Report, as time is valuable to many who are present.

The support the Fund has received during the past twelve months is extremely satisfactory, and we have to thank about 250 subscribers who sent their subscriptions to the Hon. Treasurer direct, and to nearly as many again who gave to the Fund in local collections. For these collections we are greatly indebted to Mr. W. S. King who made the start—Mr. J. Willett quickly followed and we benefitted by £400! Other large cheques were received from Lt.-Col. Schofield, Northern Command; Lt.-Col. Brittlebank, Western Command; Colonel Anthony, Aldershot Command; Lt.-Col. Brown, The Depot, Woolwich; Lt.-Col. Stratton from the Scottish Command who has been a regular collector and contributor during the war.

Colonel Rudd from the Eastern Command began a collection which has been most satisfactorily finished by his successor Colonel Stordy; and Colonel Holmes in the Irish Command not only sent in a large cheque covering his collections, but he communicated with a staunch supporter, Mr. Ewing Johnston, who, aided by Mr. Brittain, organised the enormous ballot which resulted in a cheque for £1000 being sent to the Fund. I must not speak further upon the subject of subscriptions as our Hon. Treasurer will shortly give us her financial statement.

It was decided at the meeting held here on June 5th last year to discontinue the sending of clothing other than any woollen comforts which might be considered desirable, consequently only the following have been sent:—970 mufflers, 106 pairs of socks, 336 pairs of mittens, 68 pairs of gloves, 52 helmets, 153 caps, 10 blankets, and 60 sweaters—some 1750 woollens in all, with about 2000 handkerchiefs. Various gifts of sheets, pillow-cases, etc. were sent, with games, books, etc., to the two V.A.D. Hospitals associated with two of our Veterinary Hospitals.

The bulk of the "comforts" took the form of all kinds of games, books, notepaper, and cigarettes.

Messrs. W. H. Smith continued to forward papers and magazines weekly to Mesopotamia, Egypt, Salonika, France, Italy and, lately, Russia. These have cost about £400 which sounds a large sum, but when one thinks of the help these have been to our men, enduring all weathers from tropical sun to arctic regions, it seems to have been very well spent indeed. In addition the Camps' Library supplied us with 2000 books for which we paid the nominal sum of £1 per 100 books.

The packing has been done almost entirely by Messrs. Gamage & Co., of Holborn, they sent out the comforts in bulk to Salonika, Mesopotamia, and Egypt to be distributed as the Directors of Veterinary Service thought best. In France and Italy several large bales were sent to each of the twenty big hospitals, and one or two packages to each of the seventy-two Mobile Veterinary Sections. One package and boxes of cigarettes went to every one of the eighteen Evacuating Stations, to the four Convalescent Horse Depots, and to the three Base Depots of Veterinary Stores. Later more packages were sent out to the thirteen Mobile Veterinary Sections

with the Army of Occupation. The total charge for all this packing, supplying of crates, bales, etc., and the carriage or postage is £41 11s. 2d.

The comforts for Russia were packed by members of the Committee, and were sent free as the opportunity occurred.

Before closing I would very much like to thank all the ladies of the Committee who have so kindly helped to make the Fund continue to be the success it was during the first four years of the war, and I would particularly like to express my gratitude to Mrs. Moore—who originated the Fund—for the valuable knowledge and help she placed at my disposal. I also most heartily thank Lady M'Fadyean, Mrs. Cochrane, and Mrs. Hobday, who attended our Executive Committee meeting with the regularity that only can make consecutive work possible, and Mrs. Mosely who took over the whole of the management of the wool and the making of the woollen garments, with the most satisfactory results, and lastly, I feel we owe a great deal to our Hon. Treasurer, Mrs. Martin, who has undoubtedly had the most difficult part of the work to tackle, and the efficient way in which she has done it most fully justifies our choice of Hon. Treasurer.

Mrs. Martin (Hon. Treasurer) presented the following financial statement:—

RECEIPTS AND PAYMENTS ACCOUNT,  
1st JUNE, 1918, TO 28TH MAY, 1919.

<i>Receipts.</i>		
To Balance at Bank, 1st June, 1918	£129	14 11
Subscriptions and Donations received during the year	2313	2 3
	£2442	17 2
<i>Payments.</i>		
By Clothing, Wool and Materials	£148	2 7
Newspapers and Magazines, £398	10 0	
Games and Books	824	14 4
	1223	4 4
Printing and Stationery	10	15 0
Advertising	2	15 0
Postage, Pack'g and Sundries	2	12 8
Bank charges	17	6
	17	0 2
	£1388	7 1
Balance at Bank, 28th May, 1919	1054	10 1
	£2442	17 2

We have audited the above Receipts and Payments account for the period ended 28th May, 1919, with the books and vouchers of the R.A.V.C. Comforts Fund and certify the same to be in accordance therewith.

CALLINGHAM, BROWN & Co.,  
34 Nicholas Lane, Chartered Accountants,  
Lombard Street, E.C., 4. Hon Auditors.  
28th May, 1919.

Mr. WILLETT said he thought the fund had been most admirably administered during the past year. Administration expenses were extraordinarily low, and he was sure that all the subscribers would be very gratified to know that the money had been so excellently spent.

Mrs. BLENKINSOP mentioned that she had received the following suggestions for the disposal of the balance in the hands of the fund:—

- (i) That it should be spent on the Army of Occupation.
- (ii) That a fixed sum should be set on one side for comforts for the Army in Russia, and that the remainder should be given to the R.A.V.C. Benevolent Fund.
- (iii) That the whole of the balance should be given to the R.A.V.C. Benevolent Fund.

Col. MARTIN briefly brought to the notice of the meeting the claims of the R.A.V.C. Benevolent Fund, which he pointed out was commenced nearly twelve years ago with the object firstly of relieving distress amongst any of the Warrant Officers, N.C.Os. and men of the R.A.V.C. and their families; secondly to assist them in obtaining employment, or in any other way when they left the Army; and thirdly for the support of clubs, orphanages, institutions or any other societies having for their object the welfare of soldiers and their families. The funds were vested in four trustees, two of whom were retired officers of the R.A.V.C. and two members of the firm of Messrs. Holt, the fund's bankers, while the management was carried on by a central committee composed of administrative officers of the Aldershot Command, the Eastern Command and the London District, one officer from the War Office, and a representative from the N.C.Os. and men from the R.A.V.C. Depot. That committee was assisted by several sub-committees at all the hospitals and anywhere else where any number of R.A.V.C. personnel existed, whose duty it was to investigate cases brought before them. The objects were entirely for the benefit of the N.C.Os. and men of the R.A.V.C., the very people for whom the comforts fund was started; and he suggested there could be no better way of benefiting those people than that the surplus of the Comforts fund should be handed over for carrying on the good work of the Benevolent Fund.

The CHAIRMAN said that, as Chairman of the Comforts fund from its very beginning, he thought the suggestions that had been made for the disposal of the balance were altogether premature. Peace had not yet been signed; there was an Army of Occupation in Germany, and our forces were also in Russia, Mesopotamia, India, Egypt and other parts, consisting partly of men who required comforts for which the subscriptions had been solicited, and until all those demands had been fully discharged, he objected to the closing of the fund or of the handing over of the balance of the fund to any other organisation. To suggest such a thing was contrary to his ideas of right and justice. In his opinion the fund should be continued for another year, and if at the end of twelve months peace reigned in every part of the world, the subscribers could then with a clear conscience hand the balance over to the R.A.V.C. Benevolent Fund. Even then, he thought, in justice to the subscribers they ought to know the state of the Benevolent Fund; nothing had been said as to whether that fund required a penny. Personally, he had every reason to believe from what he had heard that the Benevolent Fund had met its obligations fully and completely in the past: but if there was reason to think that it might want more money in the future, when once the Comforts fund had fulfilled its obligations, he would be only too pleased to agree to hand the balance over to the safe keeping of the Benevolent Fund, because he knew it would be properly and thoroughly administered.

Mrs. MOORE said she was sure that everybody fully sympathised with the remarks made by the Chairman, but as the present was the Annual Meeting, nothing further could be done for a year unless the matter was brought up at the present meeting, and it was thought desirable to raise the question in view of the possibility of peace being signed at an early date. Nobody had any wish to get rid of the obligation to the men on active service, and the question had only been raised to ease matters with regard to the settlement of the business part of the fund in future. The Benevolent Fund and the Comforts Fund were worked on similar lines, and if the Benevolent Fund found they wanted more money it would be easy for them to make an application to the Comforts Fund in case of special need. But at present there was no real urgency to hand the money over to the Benevolent Fund.

Mr. WILLETT supported the President's view that it premature to deal with the matter at the present time, although he thought the ultimate residue should be handed over to the Royal Army Veterinary Corps Benevolent Fund.

Mrs. BLENKINSOP said the matter had been raised in view of a memorandum which had been received from the Charity Commission dealing with the demobilisation of war charities registered under the War Charities Act, 1916, in which the statement was made: "The Committee consider that every war charity which, in consequence of the cessation of hostilities is unable any longer to apply its funds for the precise objects entered in its register sheet, should apply to the Charity Commissioners for authority to deal with such funds."

The CHAIRMAN ruled that that statement did not apply to the Comforts Fund, because it was still able to apply its funds to the precise object for which it was formed.

Mrs. BLENKINSOP said that there was a consensus of opinion that the men did not now require so many comforts as they did before; they were very much better off.

The CHAIRMAN enquired whether the R.A.V.C. Benevolent Fund required the money.

Colonel MARTIN replied that he believed the Benevolent Fund was very well off, but it was a permanent fund, as compared with the Comforts Fund which was a temporary fund.

The CHAIRMAN thought that it would be desirable to defer any final decision with regard to the handing over of the accumulated funds for the next twelve months, and that the matter should be decided at the next Annual Meeting or at a special meeting called for the purpose.

After further discussion it was unanimously resolved, on the motion of Colonel Sturdy seconded by Mr. Willett, that the question of the disposal of the balance should be deferred until such time as the Comforts Fund was no longer required.

The Annual Report and statement of accounts having been unanimously adopted,

The CHAIRMAN, in moving a hearty vote of thanks to Mrs. Blenkinsop, Mrs. Martin, Mrs. Moore and the other ladies who had worked in such a splendid manner on behalf of the fund, said their record was a magnificent one and deserved the highest commendation of all the members of the profession. He was sure that he was voicing the sentiments of everyone when he said they were deeply grateful to the ladies for the services they had rendered.

The resolution was carried by acclamation.

Mrs. MOORE, in moving a resolution of thanks to Mr. Garnett and the civilian members of the profession for the help and assistance they had rendered to the fund, said that although it was not, perhaps, an up-to-date opinion, there was no doubt that the ladies who had worked in making the comforts fund such a great success could not have done anything without the help of the men. If the men had not given the sinews of war the comforts would not have been forthcoming, and she hoped that the civilian members of the profession who had so heartily responded to the appeals that had been made would accept the grateful thanks of the Committee for their generosity.

Mrs. BLENKINSOP seconded the motion, which was carried by acclamation, the President subsequently briefly acknowledging the compliment.

The meeting closed with a hearty vote of thanks to the Hon. Auditors, Messrs. Houghton and Brown & Coy., Chartered Accountants.

### Parasite Mange (?) Fine 21s.

At Aldershot Police Court on Thursday, June 5th, Thomas Holloway, horsekeeper to Mr. W. J. North, was summoned for a breach of the Parasitic Mange Order.

Mr. Norman Clinton defended, and pleaded not guilty.

Police-Sergeant Coole said that on the 6th May he inspected Mr. North's stables in Sebastopol Road. Defendant, the horsekeeper, was there. He inspected seven horses there, and saw a bay gelding and a brown pony. The gelding was in a very bad state, covered with bare patches where the hair had fallen off, and the hair was off the pony's neck and shoulder, but it was not in such a bad state as the gelding. In his opinion they were both suffering from mange. He asked defendant if he was responsible for the cleanliness of the horses, and he replied that he was. He stated that he had not called in a veterinary surgeon, and added, "The bay horse breaks out like that twice every year. It has been like it now for about three weeks. It's the same horse Mr. Marshall saw about two years ago, and he told us then it was eczema, and I have been treating it for that now." Both horses had been treated with a greasy preparation. Witness told him to isolate the animals, and reported the facts.

In cross-examination, the witness said that parasitic mange was contagious. He examined 20 horses in the stables, and found nothing wrong with 18 of them. He was not prepared to swear the two horses were not suffering from eczema. He had seen the pony that morning, and it appeared to be all right. It was not a bad case when he saw it. He subsequently saw Mr. North, who corroborated the statements made by the defendant.

Mr. C. Marshall, M.R.C.V.S., said that on the 7th May he examined the gelding, and found it suffering from parasitic mange. He also saw the pony, and found it slightly affected on the wither with parasitic mange, probably only a few days.

In cross-examination, the witness said he was prepared to swear the gelding was not suffering from eczema. It had been bad two or three weeks. If it was in a stall by itself, but not in contact with others, he would not expect to find any of the others infected.

Mr. Clinton said the defence was that this was not parasitic mange, and pointed out that if the disease had been so bad as alleged it was natural to assume that one or two others would be affected. He said that the pony had not been treated since the sergeant's visit, and was in the police yard open for the inspection of the magistrates.

Defendant gave evidence that the bay gelding had broken out with eczema twice a year for the last four years, and he treated it by rubbing blue ointment on: He had done nothing to the pony since May 6th except groom it.

Mr. J. R. Carter, M.R.C.V.S., of Aldershot, said he was in Mr. North's stables two or three times a week. He knew the bay gelding well, and had frequently seen it, but saw no signs of parasitic mange. It was suffering from eczema. On the 8th and 26th May he took scrapings and made a microscopic examination, and found no signs of parasitic mange. He applied the same test to the pony, with the same result.

Replying to the magistrates, the witness said there would not be a germ under every scale, and it might be possible for one man to take a scraping and find a germ and another man to take a scraping and find no germs.

Mr. J. A. Cunningham, M.R.C.V.S., Guildford and veterinary inspector for the Borough of Guildford, said he inspected the two animals on the 15th May. He took two scrapings from the pony, and on microscopic examination found no parasite.

Because you find one parasite does it follow the horse is suffering from parasitic mange?—I should say a stray parasite does not constitute the disease.

He examined the bay on the same date, and came to the conclusion it was suffering from some form of eczema.

In cross-examination witness said he would not condemn a horse on the evidence of one parasite. He had frequently come across eczema, which was comparatively common, and it is comparatively common for a horse to break out with eczema once or twice a year.

Replying to the Chairman, he said that from the appearance of the skin, if it had been parasitic mange, it would have required treatment for three months. Blue ointment was used for eczema and parasitic mange.

The magistrates convicted and imposed a fine of 21s, the Chairman saying they must accept the positive evidence that one germ was found.—*Aldershot News*.

#### The Control of Contagious Abortion.

The Board of Agriculture, as at present advised, thinks that a material reduction in the prevalence of abortion in cattle by means of administrative Orders is only to be looked for if such Orders include provisions for enforcing restrictions on the movement of every cow found on infected premises at the time of each outbreak for a long period thereafter, together with the compulsory slaughter of every cow which had aborted. Moreover, such drastic measures, even if practicable, could not be relied on with certainty to secure the eradication of abortion.

These conclusions are based on the following facts, which have been brought out by the study of the disease:—

- The most important factor in the spread of abortion is the pregnant cow on infected premises which gives no indication of infection; the movement of every such animal would have to be controlled.
- Many infected cows do not abort, but may nevertheless be infective to others, so that the visible act of abortion cannot be made the standard for control, and owners would not be in a position to report such infective cows, as they could not identify them.
- A cow infected by natural infection is a potential carrier of infection for so long a period that the necessary restrictions on movement would place insupportable burdens on owners.

With this information before them, the Board are of opinion that the best interests of farmers and breeders would be served by an educational policy advocating general hygienic measures which may be taken by owners themselves for the prevention and control of abortion, and also by action designed to minimise the losses in badly affected herds by means of the artificial immunisation of animals against the disease before pregnancy. With this purpose in view, the Board are prepared to continue the issue of the vaccine prepared at their laboratory at New Haw, Weybridge, which is already being used widely by owners having infected herds, and to supply advice to the owners of infected herds suitable to the special circumstances of each case.

The Board are aware of the general feeling in favour of an Order prohibiting the exposure in a public market of at least animals which have recently aborted. Such an Order could not however, be made effective in view of the difficulty indicated above of diagnosis of the disease in many of such animals in the markets.

#### OBITUARY.

Colonel R. POYSER, D.S.O., F.R.C.V.S., late R.A.V.C.  
Graduated, Lond: April, 1864.  
At Charlton, Kent, on 4th June, Aged 77.

#### BIRTHDAY HONOURS.

The King has been pleased, on the occasion of His Majesty's Birthday, to give orders for the following appointments to the Most Honourable Order of the Bath, for services rendered in connexion with the war. (June 3):—

C.B.

Maj.-Gen. L. J. Blenkinsop, D.S.O.

ORDER OF ST. MICHAEL AND ST. GEORGE.

K.C.M.G.

\* \* \* \* \*  
Col. and Hon. Maj.-Gen. (T. Brig.-Gen.) John Moore, C.B., C.M.G., F.R.C.V.S.

#### ORDER OF THE BRITISH EMPIRE.

The King has been pleased, on the occasion of His Majesty's birthday, to give orders for the following promotions in, and appointments to, the Most Excellent Order of the British Empire for valuable services rendered in connexion with military operations in France:—

C.B.E. (Military Division).

Cranford, R. L., Lt.-Col. (A/Col.) F.R.C.V.S. Hunt, F. W., Lt.-Col. and Bt.-Col. (T.Col.) C.M.G. Newsom, A. C., Col. C.M.G. Pallin, W. A., Maj. (T.Col.) D.S.O. Perry, E. M., Maj. (T.Lt.-Col.) F.R.C.V.S., T.F. Rudd, T. W., Lt.-Col. (T.Col.) Tatam, W. J., Lt.-Col. (A/Col.) C.M.G. Wadley, E. J., Maj. and Bt. Lt.-Col. (A/Lt.-Col.) D.S.O.

O.B.E. (Military Division).

Anderson, R. G., Maj. T.F. Anderson, T. A. I., T.Capt. Bowhay, A. B., Capt. (A/Maj.) Campbell, D., T.Capt. Clay, F. S., T.Capt. Coombs, F. M., T.Capt. Craig, T., Capt. T.F. Edwards, J. A., T.Capt. Fisher, O. S., Maj. (A/Lt.-Col.) Foster, A. N., Capt. (T.Maj.) T.F. Franklin, E., Maj. T.F. Gamble, H., Maj. (A/Lt.-Col.) T.F. Harper, R. T., T.Maj. Hearne, E., Capt. (A/Maj.) Hibbard, T., Maj. T.D., T.F. Jones, J. L. C., Capt. (T.Maj.) T.F. Jones, J. H., Capt. T.F. Keppel, J. J. G., Capt. S.R. Knott, G. P., Maj. (A/Lt.-Col.) Lord, H. H., Capt. T.F. Machonachie, T.Capt. C.O., M.C. MacDonald, D., Maj. McDougall, W. A., Maj. (T.Lt.-Col.) D.S.O., (R. of O.) MacKenzie, A. Capt. T.F. Marriott, S. W., Capt. (A/Maj.) Metivier, H. V. M., T.Capt. Miller, J. C., T.Capt. O'Kelly, J. W., Capt. (A/Maj.) Plunkett, J. F., Capt. Rees-Mogg, G. B. C., Capt. (T.Maj.) att'd. 1st Life Guards. Rockett, H. C., T.Capt. Wright, J. H., Capt. (A/Maj.) T.F. Yates, J. H., T.Capt. Dubault, J. R. J., Capt. C.A.V.C. Preston, M. J., Capt. C.A.V.C. Tambllyn, D. S., T.Lt.-Col. D.S.O., C.A.V.C. Torvill, W. F., Capt. C.A.V.C. James, E. S., Maj. A.A.V.C. Macindoe, R. H. F., Maj. A.A.V.C. Edgar, P. M., Maj. N.Z.V.C. Reid, H. A., Maj. (T.Lt.-Col.) N.Z.V.C.

*For Services in Italy.*

Carroll, P. A., T.Capt. Hilliard, J. J., Capt. (A Maj.)

*For Services in E. Africa.*

Hornby, H. E., Capt. S.A.V.C.

*For Services in Mesopotamia.*

C.B.E. (Military Division).

Wood, W. A., Maj. and Bt. Lt.-Col. (T.Col.)

O.B.E. (Military Division).

Lawrence, C. J. R., Capt. Nicholl, E. Mc M., Capt. (T.Maj.) Reynolds, E. B., T.Capt. (T.Maj.)

M.B.E.

Sutton, T. J., T.Qrtmr. and Lt.

*Home Services.*

C.B.E. (Military Division).

Martin, E. E., Lt.-Col. (T.Col.) C.M.G., F.R.C.V.S. Sturdy, R. J., T.Maj. (A/Col.) D.S.O.

T.Capt. Penhale, R. H., Capt. Peatt, E. S. W., Capt.  
Thrall, P. R. A. Capt. (A/Maj.) T.F.

*For Services in Egypt.*

## O.B.E. (Military Division).

Fail, F., Maj. (T.Lt.-Col.) Gordon, A. de R., T.Capt.  
(A/Lt.-Col.) D.S.O. McIntyre, P., Capt. (T.Maj.) T.F.  
Mason, F. E., Maj. E.V.D., Rabagliati, D. S., T.Capt.  
Williams, H.B., Capt. S.R.

## WAR OFFICE, June 3

The King has been pleased, on the occasion of his  
Majesty's Birthday, to approve of the following rewards  
for distinguished service in connexion with Military  
Operations in France and Flanders (June 3):—

## TO BE BREVET LT.-COLONEL.

Maj. (A/Lt.-Col.) J. A. B. McGowan. Maj. (A/Lt.-  
Col.) C. E. Steel.

## TO BE BREVET MAJOR.

Capt. (A/Maj.) T. Bagshaw. T.F. Capt. (T.Maj.) A. A.  
Pryer, D.S.O. Capt. (T.Maj.) W. N. Rowston.

## THE MILITARY CROSS.

T.Capt. W. Adamson, att'd. 4th D.A.C., R.F.A.  
T.Capt. T. Gordon. Capt. E. J. Laine, 1/1 W. Lances.  
Mob. Vet. Sec., T.F.

*Home Services.*

## TO BE BREVET MAJOR.

T.Capt. W. Denington. Capt. A. G. Saunders, T.F.

*For Services in the Balkans.*

## TO BE MAJOR.

T.Qrtmr. & Capt. C. M. Taylor.

*For Services in Egypt.*

## TO BE BREVET LT.-COLONEL.

Maj. (T.Lt.-Col.) E. P. Argyle, D.S.O.

## TO BE BREVET MAJOR.

Capt. (T.Maj.) M. P. Walsh.

The following Despatch has been received by the  
Secretary of State for War:—

General Headquarters,  
British Salonika Force,  
Constantinople.  
9th March, 1919.

Sir,—I have the honour to submit herewith a list of  
names of the Officers whom I desire to bring to your  
notice for their distinguished and gallant services during  
the period from 1st October, 1918, to the 1st March,  
1919.

I have the honour to be, Sir,

Your obedient Servant,

G. F. MILNE, Lieut.-General,  
Commanding-in-Chief, British Salonika Force.

\* \* \* \* \*

Glass, T.Capt. (A/Maj.) J. N. (Staff). Brear, T.Capt.  
N. Hopkin, Capt. (A/Maj.) F. T.F. MacQueen, T.Capt.  
L. H. Mullany, Capt. J. (T.F.) Northcott, T.Capt. C. S.

Peatt, Capt. E. S. W. Penhale, Capt. R. H. (T.F.)  
Taylor, Qrtmr. and T.Capt. C. M. Thrall, Capt. (A/Maj.)  
P. R. A., (T.F.)

The following despatch has been received by the  
Secretary of State for War:—

General Headquarters, Italy 18th January, 1919.

Sir,—I have the honour to submit a list of names of  
those Officers, Ladies, Non-commissioned Officers and  
Men serving, or who have served, under my Command  
during the period 15th September, 1918, to 31st Decem-  
ber, 1918, whose distinguished and gallant services and  
devotion to duty I consider deserving of reward.

I have the honour to be, Sir,

Your obedient Servant,

CAVAN,

General, Commander-in-Chief, The British  
Forces in Italy.

\* \* \* \* \*

Hilliard, Capt. (A/Maj.) J. J. (Staff).

**Cruelty Charge at Coalville—Dismissed.**

Daniel Sitdown (53), fruiterer, Coalville, was sum-  
moned for cruelty to a horse at Coalville, on April 29th,  
and also for illegally working a horse sent for slaughter,  
on May 1st.

Mr. J. F. Jesson (Ashby) appeared for defendant, who  
pleaded not guilty in both cases.

P.C. Robertson said he saw two boys working the  
horse with a chain harrow in defendant's field. It was  
lame in both fore legs, and in poor condition. It seemed  
very distressed and the boys used a stick to urge it on.  
Witness saw defendant, and he said he knew the horse  
was working. He said he had the horse a few days ago  
from Mr. Josiah Kemp, who told him it could work a bit  
on the land, though he (defendant) intended to kill it.  
The horse appeared to be a very aged animal—25 years  
at least.

By Mr. Jesson: His evidence related to April 29th.  
He did not see it working on May 1st. He had no  
veterinary knowledge, but had worked among horses in  
the Royal Artillery, and knew that the horse must have  
been in pain.

Albert Smith, R.S.P.C.A. Inspector, of Leicester, said  
the animal was very old, and in a worn-out condition.  
It was lame in both fore feet, which were deformed, and  
was totally unfit for work. He saw defendant, who said  
he did not think it would hurt the horse to do a bit of  
work on the land. Witness told him he had seen Mr.  
Kemp, who said he sold the horse to him for slaughter.

Answering the clerk, witness said he did not see the  
horse working on May 1st. It was the 29th of April  
when the horse was worked, and witness visited the  
premises on May 1st, and the animal had not then been  
slaughtered.

The clerk said the summons stated the horse was  
worked on May 1st.

Witness asked for the summons to be amended to  
April 29th in respect of the second charge. The Bench,  
however, dismissed the second charge.

In reply to Mr. Jesson, the inspector said an animal  
in that condition could not be worked without pain.

Josiah Kemp, grocer, Coalville said he sold the ani-  
mal, an aged gelding, to the defendant, as he did not  
wish to work it any longer on the road. The horse was  
about 24 years old.

By Mr. Jesson: He told Sitdown he did not think it  
would hurt the horse to do a little harrowing, but if he  
(defendant) worked it, it would be at his own risk.

Defendant said the horse was only working for about  
one hour and half with a small harrow. He did not  
notice it was lame, and was not aware it was in pain.

Wm. E. Little, veterinary surgeon, locum tenens for Mr. H. E. Powell, Coalville, said he was called by Mr. Sitdown to see the horse the day it was worked. The animal, though having deformed feet was not in pain, and galloped round the field while witness was there. The Bench dismissed the case, and on the application of the Inspector, they remitted the Society's costs—*Coalville Times*.

#### Adulterated Foodstuffs.

The following notes are from the half-yearly report of Dr. J. F. Tocher, Analyst to the Highland and Agricultural Society, recently submitted to the directors.

"A sample which was labelled 'meat meal' was analysed and was found to be really a sample of fish guano, wholly unsuitable for feeding purposes on account of the high proportion of oil present, and also on account of its 'high' character. The proportion of oil present was 13 per cent., while the albuminoids amounted to 38 per cent. The member wished to know whether the article was suitable for feeding poultry and pigs. It was reported to be wholly unsuitable for this purpose, but of value as a fertiliser, containing as it did 6 per cent of nitrogen and 7 per cent. of phosphates.

A sample labelled 'flour sweepings' was quite evidently flour which had been rejected for human use on account of its lumpy condition and the proportion of moisture it contained. It was otherwise quite sound with an excess of only 5 per cent. of moisture over the amount generally present in flour for bread making. Compared with the market price of home flour it was found the flour sweepings cost £2 16s per ton more than the flour used for baking purposes. This shows the effect of control in the price for human consumption and of the absence of control should the article be of agricultural value and just fail to reach the standard required for human use.

#### POISONS.

Several samples of internal organs of animals were sent in for examination for poisons. A very valuable sheep-dog was found to have been poisoned by crude carbolic acid.

A sample of cattle salts was found to consist of about 90 per cent. potassium nitrate and 10 per cent. sulphate magnesia. These salts were administered to a cow in the belief that the dose was Epsom salts, the cow died

after a very brief illness—evidently due to the excessive amount of nitre administered.

#### GRASS SICKNESS IN HORSES.

The stomach of a horse was sent in for examination by a member of the Society just beyond the Border. No trace of any vegetable or mineral poison was found in the stomach, the villous portion of which was found to be in a very inflamed condition. The post-mortem appearance generally corresponded closely to the appearance exhibited in post-mortem examinations of horses which had died of the disease now popularly known as 'grass sickness.' On enquiry it was ascertained that over twenty horses in the neighbourhood had died from similar causes. This scourge has for the past few years occurred during the months of May and June of each year in certain parts of Forfarshire and Perthshire. The Directors of the Society, recognising the seriousness of the outbreak and loss to farmers, arranged some time ago to conduct an investigation into the cause of this scourge. During this season two horses have already succumbed. The symptoms, environmental conditions, and post-mortem appearance of every case are being thoroughly investigated by a body of experts under the direction of the Society, with the objects of ascertaining the cause and of checking and, if possible, stamping out this disease."—*North British Agriculturist*.

#### Milk Producers and Ministry of Health.

At the meeting of the Council of the British Dairy Farmers' Association held at 28 Russell Square, London, W.C., on Wednesday, 4th June, Lord Bledisloe, K.B.E., President, in the Chair:—

A resolution moved by Lord Strachie and seconded by Sir Sydney J. Pocock, and with a slight amendment by Lord Bledisloe supported by Mr. James Sadler, was unanimously carried and ordered to be sent to Dr. Addison as follows:—

"That with a view to assisting the Minister of Health in securing for the Public a pure and sufficient supply of milk and other dairy products under the provisions of the Milk and Dairies (Consolidated) Act, 1915, the Minister be requested to appoint a Milk Producers' Consultative Committee to advise him in relation to such matters."

The next meeting of the Council was fixed to be held on Wednesday, July 2nd.

VOL. XXXI.

## POULTRY AND RABBIT PRACTICE.

One can hardly yet guess how much of the great popular increase in breeding and rearing of poultry and rabbits is likely to last. Much of it will probably continue for some years at least : and perhaps, like other economic changes arising in the recent years, it may become to a large degree permanent. Poultry and rabbits are among the native economic resources which had been long neglected and were forced into notice by war conditions. That compulsion has passed ; but it may have left a general recognition that such industries ought never to have been neglected and ought now to be maintained. If a considerable section of the nation learns that lesson we shall retain a minor line of veterinary work.

Until quite recently, most practitioners were seldom, if ever, asked to treat poultry and rabbits, but latterly it has become a much more frequent occurrence. Minor branches of our work though both these undoubtedly are, they are likely to be profitable side lines to many of us ; and we are certainly the proper men to take them up. No training affords so solid a ground from which to commence their further study as the veterinary. It must, however, be remembered that such detailed study is not merely advisable but absolutely essential for most of us, if we are to become experts in the diseases of these comparatively new patients.

Text-books and the school curricula do not help us very much with either patient ; as their instruction, though good as regards a few specially important diseases, goes little beyond those. Much remains with regard to both patients which can best be learned by practice and the intercommunication of clinicians. The task before us is not unlike the one when the profession generally first seriously took up the treatment of dogs and cats. Most practitioners in those days, knew far too little of the diseases of both animals, especially the latter ; but the deficiencies were soon made good. What we did with dogs and cats we can do again, as some already have done, with poultry and rabbits. If we study them, they are likely to remain a distinct addition to veterinary resources in many districts ; but they demand some study.

## POLITICS, PROPAGANDA, AND PROFESSIONAL ORGANISATION.

The interesting remarks of Mr. H. C. Wilkie are deserving of more than passing attention by the rank and file of the profession. It has always appeared to me that those gentlemen who so often bewail the lack of our social status rarely, if ever, contribute anything of a scientific nature for the advancement of the profession, or offer any suggestions of a progressive character which, if acted upon, would tend to lift us out of that slough of despond and state of social negation in which they affirm we have been engulfed from time immemorial. It is of no use to grumble over our supposed lack of social advantage and at the same time do nothing, or attempt nothing to alter the situation. I think we may safely allow "Watchman" to stew in his own literary juice, and neither begrudge him his shroud of anonymity, nor trouble about his mud baths.

To me the greatest need of the veterinary profession in this country to-day is scientific organisation. There is a great levelling force acting on all the professions at the present time ; and in the coming decades, mental equipment and scientific achievement will be the potent factors in advancement. In the State of the future men will not stop to enquire whether a man's father was a lawyer, a parson, or one of the old landed gentry ; they will be more eager to discover his ability or utility as a citizen.

We, as veterinary surgeons, have no central standing organisation to initiate or carry through any matter of importance, either in the field of original inquiry, in practical politics, or propaganda work. Take the case of "Naval Ill," the subject embraces some of the most important problems in hippo-pathology, and yet we leave it to some Scotch farmers to form a committee to investigate the disease.

A National Association having a whole-time secretary is one of the requirements of the day. The present National is a mere passive institution ; it possesses no drive, and plays a small part in national work. It gives no lead and has no voice. Far from this, it should be, so to speak, the organising brain of the profession, and the secretary, devoting his whole time to the work, would keep in touch with the different branches and thus carry through matters of national and local interest with the necessary weight.

It (the National) should also associate itself with the organisation of centres for clinical research, preferably in connection with the existing Colleges. Here practitioners could have reports on pathologi-

cal material supplied, bacteriological examinations carried out, autogenous vaccines prepared, and other work done such as agglutination tests, etc. Much pathological material at present running to waste would thus become available for teaching purposes. An association of this kind would naturally have its official journal, and other fields might be enumerated in which improvement or expansion might take place, but enough has been said to indicate the lines along which I think advance should be made. Much money would be required, and perhaps too few veterinary surgeons would lend support to render the suggestions practicable, but there should be a return for the outlay in increased efficiency and earning power of the individual practitioner, enlargement of professional outlook, a fuller recording of clinical experience, and less provincialism; while post-graduate teaching facilities would be greatly added to.

If the nineteenth century belonged to the town veterinary surgeons, the twentieth will belong more largely to those in the country, and it behoves the latter to organise themselves and do some share of scientific work in the future. Specialisation and again divisions in specialisations in scientific enquiry is the tendency manifest to-day. Diseases are investigated by bodies of men among whom there is team work, and collective enquiry. The biochemist, the bacteriologist, the morbid anatomist, and clinician must assist each other in working out the natural history of diseases, either in man or animals, for even many so-called simple maladies can no longer be investigated by individual workers, so complex are the problems presented in many instances.

Whether British Veterinary Science will see its way in the immediate future to develop and maintain some sort of central and powerful organisation to assist in its evolution remains to be seen. The outlook is not so dark as the pessimists would have us think. The horse dealing influence and the forge are passing away—not the least of the benefits conferred upon the profession by that great time saver the motor. To-day there is more leisure and more work done. The latter is better performed, and becomes more pleasant, and the animal owner is better satisfied. Recognising as never before the limitations of medicine so far as the giving of drugs is concerned, he is quick to appreciate the benefits of management and good advice.

Provincial veterinary medicine has been almost revolutionised in the last ten years, and its votaries will always be in a different position from those practising human medicine and surgery in similar areas. Patients of the latter may quickly obtain the assistance of specialists from afar, or be themselves transported to operating centres; while the veterinary surgeon practising in almost any district may find himself in charge of an animal worth hundreds or possibly thousands of pounds, and no specialists available to share his responsibilities. No longer do we find pedigree stock in a few centres only; small studs and herds containing stock of great value are springing up all over the country. The veterinary surgeon, therefore, more than the

medical man, will in future require as a part of his equipment a centre where any necessary pathological investigations may be carried out, and for this he should be prepared to pay to some extent, and not, as now, rely for help on the good nature of already over-worked professors.

A progressive spirit is necessary to meet the changing times, and more inter-communication between the members of the profession in different countries should be welcomed. An international fellowship in veterinary medicine may be in the future no idle dream, for has it not already materialised in the medical world?

F. T. HARVEY.

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### POISONING BY MERCURIALIS PLANTS.

J. A. Hoffmann, in the *Berliner Tierärztliche Wochenschrift* of 1918, gave an account of *Mercurialis* poisoning. After summarising the existing knowledge of the subject, both as regards naturally occurring cases and experimental ones, he described eight cases which occurred about the end of 1917 and the beginning of 1918. These were in horses which had eaten hay containing great quantities of *Mercurialis annua*.

The symptoms consisted in grave depression of the sensorium, yellow or brownish-red tint of the conjunctiva, refusal of food and drink, suppression of the intestinal function, uneasiness, difficult elimination of a small amount of thick brownish-red urine, sensitiveness to pressure of the renal region, rigidity of the hind quarters, augmentation of the frequency of the respirations (up to 20 per minute), and of the pulse (up to 90 per minute), and augmentation of the temperature up to 103.1° F.

The therapy recommended is aloes (30 grammes) and arecoline (0.05 gramme), with Priessnitz packings to the abdomen and warm poultices to the renal region. If the heart is weak, the administration of digitalis is advised.

In five horses the symptoms were slight, and disappeared after three days; all these animals resumed their accustomed work after eight days more. Two other horses, in which the poisoning was grave, only recovered after two and three weeks respectively. The eighth horse died in twenty-four hours with symptoms of acute colic, and presented post-mortem lesions of pronounced gastro-enteritis, acute hæmorrhagic nephritis, and torsion of the colon.

*Mercurialis* preserves its toxicity even when it has dried. There are animals which show a strange individual predisposition to the toxic action of *Mercurialis*, and exhibit symptoms of intoxication after ingesting an insignificant quantity of it. Others are much more resistant to the poison.

According to Schulz, the toxic principal is *mercurialin*, which acts upon the muscles and upon the nerves of the intestine and the bladder, and also upon the heart. The red tint which the urine assumes in consequence of the ingestion of *Mer-*

*curialis* is due, in all probability, to an indigo-red pigment contained in the plant. In all cases of *Mercurialis* poisoning, the prognosis should be guarded.—(*La Clinica Veterinaria*).

(*Mercurialis annua* is found in England, though it is not so generally common in the country as dog's mercury [*M. perennis*])—*Transl.*

#### ANTHELMINTHICS IN THE HORSE,

Stall, Wilson, and Wigdor published an article upon this subject in last year's *Journal of the American Veterinary Association*. The intestinal *sclerostomes* or strongyles of the horse are difficult to expel; and the authors have experimented with various drugs, including sulphate of iron and tartar emetic, turpentine, and oil of chenopodium, for this purpose. They conclude that sulphate of iron and tartar emetic are inefficacious against intestinal strongyles, and that tartar emetic also often causes grave cases of enteritis. Turpentine (60 grammes, followed immediately by a litre of olive oil) is more active; and a single dose causes the expulsion of about 50% of the parasites. Oil of chenopodium in the dose of from 8 c. c. to 10 c. c. has little action; but double that dose is very efficacious, causing the expulsion of over 95% of the parasites. The authors therefore conclude that the oil of chenopodium is the best anthelmintic against equine intestinal strongyles, and that turpentine comes next to it.

To free the horse from ascarides is much more difficult. With turpentine, or with oil of chenopodium in doses of from 16 c. c. to 18 c. c., some success was only obtained in a very limited proportion of cases. Against oxyurides, better results were obtained with turpentine (60 grammes followed by olive oil) and with oil of chenopodium.

W. R. C.

#### MIDLAND COUNTIES VETERINARY MEDICAL ASSOCIATION [NATIONAL V.M.A.—NORTHERN BRANCH.]

The quarterly meeting was held at the Grand Hotel, Birmingham, on Tuesday, May 13th, Mr. J. Malcolm, President, occupied the chair. There were also present: Messrs. W. H. Brooke, Handsworth; R. H. Over, Rugby; L. C. Tipper, Birmingham; T. H. Hobson, Leicester; J. Martin, Wellington; J. W. Conchie, Kidderminster; J. Young, Birmingham; J. O. Powley, Sutton Coldfield; Brennan De Vine, Birmingham; J. R. O. Jones, Gloucester; H. W. Stevens, Kidderminster; L. W. Heelis, Solihull; S. M. Woodward, Birmingham; H. A. Turner, Derby; J. L. Cormack, Coventry, and the Hon. Sec. Mr. H. J. Dawes, West Bromwich.

Apologies for unavoidable absence were announced from Professor Dewar, Messrs. J. R. Carless, J. M. Whyte, W. W. Grasby, F. L. Gooch, P. C. Woolston, C. J. Clifford, S. J. Marriott, J. J. Burchnell, R. L. Phillips, T. J. Brain, C. F. Parsons, C. E. Dayus, T. Spencer, A. Over, W. Trigger, R. C. Trigger, and others.

The minutes of the previous meeting were read and confirmed and the rules of the Association were also read by the Hon. Sec.

Among the correspondence was a letter from the Secretary of the Anglo-Franco-Belgian Veterinary Relief

Fund, acknowledging "with sincere gratitude" a donation of £10 voted at the previous meeting, and also letters from Mr. J. Blakeway and Mr. Carless, thanking the Association for their resolution of condolence.

#### THE MINISTRY OF HEALTH BILL.

The Hon. Sec. recalled the fact that at the previous meeting a committee was appointed to urge upon the Parliamentary Committee of the Royal College of Veterinary Surgeons the necessity of watching the progress of the Ministry of Health Bill with a view to safeguarding the interests of the profession. He had since received the following letter from Mr. Fred Bullock, Secretary of the Royal College, dated March 21st:—

"I brought your letter with the accompanying resolution of the Midland Counties Veterinary Medical Association before a special meeting of the Parliamentary Committee held yesterday. The Bill was also circulated to the members of the Committee and was very carefully considered. Mr. Malcolm's letter to Sir John M'Fadyean in which he describes more in detail the desires of your Association, was also considered. The Committee instruct me to state that as the present Bill does not enact any new legislation with regard to the matters raised in Mr. Malcolm's letter, but merely brings together under one department the functions that are being performed under existing Acts of Parliament, no opportunity is given for raising such questions on the present Bill. The Bill, however, is being carefully watched, and a resolution was passed urging that a veterinary surgeon should be included on the Consultative Committee to be set up by Clause 9. An amendment to this effect will be proposed when this Clause is reached."

The PRESIDENT said he understood that there had been several meetings of the Parliamentary Committee of the Council watching the position. Mr. Bullock's letter shed rather a new light on the matter and he had no reason to doubt that their interests were not being neglected. If any new legislation was brought up, the Parliamentary Committee might be trusted to take the necessary action.

Mr. TIPPER said the Bill had been before the Chambers of Agriculture in the country, but unfortunately, owing to pressure of other business it did not receive much consideration. There was a general want of knowledge on the subject, and he thought if any similar Bill came forward in future it would be wise to consult agricultural associations, as their interests often coincided with those of the veterinary profession.

#### QUACK MEDICINES AT SHOWS.

The Hon. SEC. brought forward a letter he had received from the Derbyshire Veterinary Association, who had passed the following resolution:—

"That veterinary surgeons refuse to act in a professional capacity at Live Stock Shows where vendors of animal medicines and surgical appliances are allowed to have stands for the purpose of exhibiting or offering such articles for sale, and also that veterinary surgeons attending officially at Live Stock Shows shall receive a fee."

Mr. OVER questioned whether they could take up a position of that kind. Veterinary medicines sold in that way probably did the profession no good, but the trade was within the law.

The PRESIDENT thought very few members of the profession would refuse to act at shows on that account. At all the shows he had visited during the last forty years there had been stands for the sale or exhibition of veterinary medicines, and he did not think they would get it altered by taking up the position that was suggested by the Derbyshire Association. Personally,

he did not see his way to support the suggestion.

Eventually, on the motion of Mr. Over, seconded by Mr. Martin, it was resolved unanimously that no action be taken in the matter.

#### ROYAL SANITARY INSTITUTE.

The HON. SEC. read a letter from the Royal Sanitary Institute inviting the Association to send representatives to their annual conference to be held at Newcastle-on-Tyne at the end of July.

The PRESIDENT thought they ought to send delegates, as was done before the war. He had a personal reason for saying that, as he had been asked to preside over the veterinary section and he had consented to do so. He would like to be fortified by the presence of some members of the Association. Sir Stewart Stockman had promised to give a demonstration on rabies, which was a live subject, whilst a second subject would deal with different phases of the work of the veterinary inspector. He was going, apart from the Association, so that two others could be chosen as special delegates. He would be present in a dual capacity, as president of this Association and on behalf of the Birmingham Corporation.

It was ultimately resolved to send three delegates to the conference, the President, the Hon. Sec., and the Hon. Treasurer (Mr. W. H. Brooke), the two last-named to have their expenses paid by the Association.

#### INSURANCE FEES.

The question of fees paid by the various insurance companies for the examination of horses for insurance, the discussion of which was adjourned at the last meeting, was again raised. The Hon. Sec. said he had received a letter from Mr. T. H. L. Duckworth, of Ashbourne, regretting that he could not attend that day, but mentioning that he had now no trouble in obtaining a fee of half-a-guinea for examining animals on behalf of insurance companies.

Mr. BROOKE said he was recently offered 6/- by a company to make an examination and he told them his fee was 10/6. He got it. There was no need for them to work for the low fees they had received in the past. The work generally involved something that was almost equal to an examination as to soundness, and it was worth half-a-guinea.

The HON. SEC. said the different live stock insurance companies belonged to an association.

Several members gave their experiences. Mr. Young remarked that he had no difficulty in getting half-a-guinea now. He refused to do the work for less, and if they held out they would get what they wanted. If the companies refused to pay a proper fee they must take the risk of insuring an animal without a veterinary surgeon's examination.

The HON. SEC. said it would be a good thing for representatives of various veterinary associations to interview the companies. He was afraid that an association which took the matter up single-handed would fail.

Mr. OVER thought 10/6 for the examination of a horse under £50 in value seemed rather high. He would like to see a sliding scale, with, say 7/6 as a minimum.

Mr. DEVINE suggested that they should get into touch with the National Veterinary Association. This seemed to him to be a subject well within their province.

Mr. TIPPER, Mr. HOBSON and others shared this opinion, and eventually, on the motion of the Hon. Sec., seconded by Mr. DeVine, the Hon. Sec. was instructed to communicate with the National Veterinary Association with a view to this matter being considered at their next meeting.

*Price of Petrol.* The HON. SEC. said that at the previous meeting it was reported that some veterinary surgeons were able to obtain petrol at traders' rates, although they did not say how they managed it. The

Derbyshire Veterinary Association had written to the oil company asking whether the same privilege could be extended to the whole of the profession. The reply was in the negative.

*Subject for next meeting.* The HON. SEC. reported that the Council recommended that at the next quarterly meeting, to be held at Birmingham, Prof. O'Connor, of the Royal Veterinary College, Dublin, be asked to give an address with a practical demonstration.

This was agreed to.

#### BOARDED-OUT ARMY HORSES.

Mr. YOUNG mentioned the question of fees allowed by the Government for attending army horses that had been let out. He was formerly allowed 1d. per day per horse, with an allowance for mileage, but he was now asked to do the work for 20/- per horse per annum within a 15 miles radius and 30/- beyond, with no mileage allowance. He had written refusing to do it.

The HON. SEC. said that apart from the inadequacy of the terms, he thought the principle was altogether wrong. The Government was asking veterinary surgeons to attend horses that were in the stables of men who were probably clients of another veterinary surgeon, and that was very objectionable.

Mr. TIPPER said the point raised by Mr. Dawes was a very important one; and Mr. DeVine and other speakers expressed similar views.

Mr. OVER said the same difficulty arose in regard to the appointment of veterinary inspectors.

Eventually, on the motion of Mr. De Vine, seconded by the Hon. Sec., a resolution was unanimously carried, to the effect that the Hon. Sec. should write to the Director General of Army Veterinary Service pointing out the difficulties that are likely to arise through one veterinary surgeon trespassing on the practice of another, and at the same time complaining of the inadequacy of the fees that are paid.

#### PERIODIC OPHTHALMIA.

By BRENNAN DEVINE, M.C., F.R.C.V.S., D.V.S.M., (Vict.)

When I was invited by our President, Mr. Malcolm, a fortnight ago, to contribute a paper on Periodic Ophthalmia for discussion at this meeting, I hesitated a good deal, as I knew I could not give much time to the writing of a paper, and further, I unfortunately have not now in my possession various notes which I made from time to time upon the great number of cases I was able to observe whilst serving in France. However, I trust my remarks will be of some interest to you all, and I hope to hear a good discussion on the subject.

I will endeavour to describe the disease as far as I can from a practical point of view. The opinions which I give are formed principally as the result of my own experience during the past two or three years. To my knowledge periodic ophthalmia has been prevalent among horses in the British Army in France since the summer of 1917. As many army horses are now being repatriated to England, I consider this disease one of the most important for us to study, for I think it feasible to expect that some affected animals may be brought to this country from France.

We know from the history of the disease that it was prevalent among horses in England about the middle of the last century. If outbreaks occur now in this country it will be necessary for all of us to be able to readily recognise the disease, so that we may take energetic steps for its immediate suppression and ultimate eradication. As I have suggested that we may possibly have an outbreak of periodic ophthalmia in England, I hope this will not be taken as an expression of disparagement of the Veterinary examination of horses before leaving France. I know it is difficult to diagnose the disease except in its active stages, and from its intermittent

nature it is not always possible even during a long period of quarantine to definitely say if an animal is free—especially in the interval following the first attack.

Until comparatively recently periodic ophthalmia was believed by most observers to be due to the irritation of the eye caused by dust or other foreign bodies carried by the wind. As far as my experience goes, periodic ophthalmia is as prevalent in winter as in summer. It may effect any breed of horse, but is comparatively rare in mules.

During the first eighteen months or two years of the war, when the great majority of the animals with the Expeditionary force in France were British horses, periodic ophthalmia was rarely seen. During the early half of 1917, following the German retreat on the Somme, the British Army occupied a large tract of country which had previously been occupied by the German army. About the same time we had a lot of foreign imported horses sent out from England. A few months afterwards I found many cases of periodic ophthalmia among the horses in units under my Veterinary charge. I do not know if the disease was introduced by the new horses we received, or if it was contracted from premises previously occupied by German horses. I merely mention these as possible sources of infection. So far as I know the channel of infection and method of spread has not yet been definitely ascertained. All attempts to inoculate animals with the discharges from infected eyes by depositing on the surface of the eye or injecting subcutaneously in the neighbourhood of the eye of a healthy animal have so far failed. Possibly infection takes place by inhalation or ingestion, more likely the latter. If this is the case it is not difficult to understand animals contracting the disease from infective material in certain specific areas, e.g. the war stained insanitary area of the Somme district, patches of which have been overcrowded with horses for several years.

Thanks to the original work carried out by Capt. Thos. Dalling, R.A.V.C., of No. 2 Vety. Hospital, Havre, we now know the definite causal organism of periodic ophthalmia, which has been found in the optic nerve. This is described by Dalling as a coccobacillus and named the "Nerve Bacillus," 1.2 microns long by .5-1 micron wide. By intra-venous injection of old culture in broth of the bacillus, guinea pigs and horses have been experimentally infected. Further details of the bacillus are given in an article by Capt. Dalling in the *Veterinary Journal* for Jan., 1919.

#### SYMPTOMS.

The disease may manifest itself in a variety of forms. The attack in every case comes on very suddenly, often seen first thing in the morning, although the horse looked perfectly normal the day before. It may affect one or both eyes; in later attacks it usually affects both. One eye may escape even four or five attacks, but finally it is involved. The local symptoms vary in different animals. In some corneitis is developed whilst in others iritis is the predominant symptom.

At the beginning of an attack the eyelids are inflamed and very painful. When corneitis is present the animal is very frightened to have the eyelids touched. The first thing one notices is the closed eye, lachrymation; on opening the lids, which it is necessary to do very gently, one finds the cornea is blurred and the conjunctiva inflamed. The aqueous humour has a grayish sediment in it. Later there is a grayish infiltration of the cornea, generally starting at the periphery end, spreading towards the centre. There is general constitutional disturbance for the first three or four days of the attack. During this period the temperature will rise to 103° or 104°F. or even in some cases to 105° or 106°F. About the fourth or fifth day of an attack the temperature subsides. The attack usually lasts ten days to three weeks.

At the end of the attack inflammatory symptoms disappear, the cornea clears up and in most cases the eye becomes apparently normal, but occasionally one finds cases in which there persists a very slight milky-white cloudiness in the cornea.

In the other form iritis is the outstanding symptom. The upper eyelid is swollen, but not quite so badly inflamed as in the keratitis form. The eye is kept closed. At first there is slight turbidity of the aqueous humour: the pupil is contracted, there is immobility of the iris, and synechia. The aqueous humour becomes opaque and yellowish green in colour. As in the other form, there are febrile symptoms and general constitutional disturbance. There is at first defective vision, and about the third day of the attack there is temporary blindness which persists for the duration of the attack, usually lasting about two to four weeks. At the end of the attack the aqueous humour clears up, and the pupil becomes less contracted save in those cases where you have synechia. In either the Corneitis or Iritis form, the later the attack, the greater the amount of inflammation present and the longer the duration, until with the fifth or sixth attack, or even the eighth attack, permanent blindness is developed. In this case the blindness is due to degeneration in the optic nerve and retina, whereas the temporary period of blindness in the previous attack is due to the opacity in the cornea or aqueous humour.

When permanent blindness has taken place, there is no further symptom of pain; there is often Glaucoma, and if pressure is applied to the eye it does not retract. When corneitis is the prominent symptom ulceration of the cornea may take place, and blindness supervenes even in a primary attack. Ordinary ophthalmia is not nearly so persistent, and in such cases you do not find such great constitutional disturbance as in the periodic form. The attack does not last so long, and it is not apt to recur. In true specific ophthalmia I consider the prognosis unfavourable in every case. In my opinion in all cases of periodic ophthalmia the final result is blindness, and this takes place usually in the 6th, 7th or 8th attack. In the 1st or 2nd attack the local symptoms in the eye disappear in two or three weeks, and the animal is apparently cured. The thickening and inflammation of the eyelids subsides, but there is left a peculiar wrinkling of the upper eyelid. The interval between attacks when active symptoms occur, varies from two to six months. Owing to the intermittent character of the disease diagnosis is sometimes difficult, but each attack leaves behind certain signs which persist. The most common is the peculiar wrinkling of the upper eyelid. The head of a horse that has had an attack is frequently carried at that angle assumed by one eyed horses.

When corneitis has been present there often remains a haze or bluish white cloudiness at the edge of the cornea; this is more evident after every succeeding attack. In the earlier attacks usually only one eye is affected, and comparison of the eyes is a great help in determining if the animal has had an attack. The eye which is affected is retracted more than the healthy one and for this reason appears smaller. In those cases where iritis has been present one finds on examination of the eye a yellowish or greenish yellowish light is reflected from below the lens. Opaque lines or spots may be detected on the capsule of the lens or in the aqueous or vitreous humour. After the second or third attack the pupil is usually contracted, this is due to adhesion of the posterior part of the iris to the capsule of the lens.

#### TREATMENT.

In spite of the unfavourable prognosis which I should give, treatment is desirable in every attack. First from a humanitarian point of view, as this is a painful

affection for the horse, and by appropriate treatment may be rendered less painful; and further the temporary blindness which place during the earlier attacks can be more readily cleared up. At present there is nothing that I know that will prevent the final result of blindness in an animal that has become infected with the disease. Further research is necessary, and when this has been carried out by our bacteriologists, I am in hopes that we shall be provided with preventative, diagnostic and curative agents. In the meantime, if we hope to keep the disease in check, it is advisable to adopt isolation and segregation.

In all cases of Periodic Ophthalmia the eye tends to clear up without any special treatment; in primary and secondary attacks this resolution may be hastened by the use of local dressings. Most of the Veterinary Officers with the Army in France whom I have asked about their treatment for Periodic Ophthalmia appeared to have a special treatment of their own. Among the more common applications used may be mentioned Calomel powder: Tr. iodine: Lugol's sol: Biniod of Hg: Belladonna ung: Atropine: Zinc chlor.: Zinc sulph.

I may say that I have seen all these drugs tried on cases. The calomel was used in the form of powder. I do not consider any drug applied in the form of powder a good thing for the treatment of affections of the eyes in horses. The blowing of the powder into the eye frightens the animal, which at the time is unusually sensitive about the eyes. This tends to make the horses so treated difficult to handle about the head. Again, if too great a quantity of such common eye remedies as calomel or acetate of lead are used, it may have a harmful effect on the eye.

In those cases of Iritis contracted pupil the use of mydriatics such as Belladonna and its alkaloid, atropine, undoubtedly have a beneficial effect. In addition to the local anæsthetic effect it dilates the pupil and tends to reduce the chances of posterior synechia. Iodine or 4% Biniod. Hg. ung. applied to the upper eyelid reduces the oedema and stimulates the surrounding lymphatics, and thus promotes a quicker clearing of the opacity in the eye in the earlier attacks of the disease. The injection of Lugol's Sol. with a hypodermic syringe into the depth of supra-orbital cavity has a similar effect. In practice the latter method is preferable to applying a counter irritant ointment to the eyebrow. Boracic acid sol. is useful in the early stages for fomenting the eye 3-4 times daily. It has an analgesic and antiseptic effect. Solutions of Zn Cl, Zn S O<sub>4</sub> or AgNO<sub>3</sub> are useful in treating the Keratitis form after the first inflammatory symptoms of an attack have somewhat subsided. In general treatment I would recommend fomentations 4-6 times a day with warm Boracic acid solution, protect the eye from strong light by means of wire cage covered with dark cloth. The custom of covering the eye by means of a piece of canvas or other cloth suspended from the brow band of the bridle or head collar should be condemned; it causes irritation of the inflamed parts already sensitive and painful, it is liable soon to become soiled and is not hygienic.

When the very acute inflammation of the eyelids has been reduced and the eye is affected with the Keratitis form, I would apply a 1% Sol. of AgNO<sub>3</sub>. If the symptoms are principally in the iris and lens I would inject 5 c.c. of Lugol's Sol. into the supra-orbital cavity every second day. This treatment reduces the period of an attack when active symptoms are present.

The general febrile symptoms would be treated in the ordinary way by giving mashes and febrifuges.

Finally there is the attack, which may be the 4th, 5th or 6th, when permanent blindness is the result; when this stage is reached further treatment is useless. There is then found on p.m. degeneration of the optic nerve

and atrophy of the retina. Cataract is a frequent sequel to the iritis forms.

Vaccines made from the Nerve Bacillus have been tried as a method of treatment. I am in hopes that this will prove valuable in the early stages of the disease. In the later stages, where there is structural alterations in the optic nerve, it is hardly conceivable that any method of treatment will be of any use.

#### DISCUSSION.

The PRESIDENT remarked that Mr. De Vine had only been home from the army a short time but had readily agreed to give his experiences on a disease they had perhaps not yet heard the last of. He took this opportunity of welcoming back other members of the forces, and probably they would be able to contribute usefully to the discussion.

Mr. OVER said the paper was so very complete that it was difficult to carry it any further at the present stage. He met with a great number of cases in France, and as for treatment, first one thing and then another was tried but none of them did much good. The trouble returned later on. Warm fomentation with boracic was as good as anything, and at least it afforded the animal most relief.

Mr. HEELIS agreed that the essayist had left little that was fresh to be said. It was his (the speaker's) experience that there was a predisposition to periodic ophthalmia with horses that had previously had any febrile trouble, such as influenza. He could not share Mr. De Vine's opinion that mules were comparatively free from the disease, because he had seen as many cases amongst mules as amongst horses.

Mr. STEVENS said the disease presented many peculiarities, breaking out in the most unexpected places and sometimes not breaking out when it was expected. It did not appear to him to be very contagious among the animals themselves; the cases were generally isolated, standing apart from each other. He could not remember any two animals standing side by side having it. He referred to a unit in France that had the disease very badly. A heavy battery which had suffered from it moved to fresh ground and another battery, apparently free from the disease, came in. The new battery had not been long in these lines before there was an outbreak of periodic ophthalmia, and in the meantime the old battery had no fresh cases on its new ground. The only suggestion he could offer was that the ground was badly affected. It must have been the ground, as they were in open lines.

Mr. POWLEY said he had no experience of the trouble, but he would like to ask whether there was any advantage in damping the food. He had seen it suggested that it was a good thing as a preventive measure. What was the result of the agglutination test in regard to the causal organism?

Mr. DE VINE: The whole thing is in its infancy yet, so that I cannot go into it to that extent.

Mr. MARTIN remarked that although he had not seen any cases, he quite expected he would do so as army horses became spread over the country.

Mr. BROOKE thought most of them must have seen periodic ophthalmia at some time or other, but they may have doubted as to whether it was specific. When he had met with such a case he had isolated it, although he never thought there was anything contagious about it. The case had generally run the course indicated by Mr. De Vine. There was effusion into the anterior chamber and adhesion of the iris to the front of the lens. He begged to differ in his opinion with regard to the value of calomel as a treatment. He had tried it in eye cases, not so much with horses as with dogs, and as a stimulant for ulcer of the cornea he thought there was nothing finer than calomel.

The PRESIDENT said he could have wished that the discussion had been more general—that more had taken part in it, but he quite realised the difficulty. This was a disease they knew very little about. With regard to the benefits of isolation, several men with whom he had spoken shared the opinion of Mr. Stevens, that the fresh case was not generally next to the animal already affected but some distance away. That seemed to suggest that the ordinary risk of contagion was not present, but that there was predisposition on the part of some animals to take the disease. Another point was the localities in which the affection was found, and he could not help inquiring whether they got cases in Italy as well as on the Somme. Was it the soil or the climate, or what was it that gave rise to the disease?

Mr. Powley added that Mr. Malcolm's last remark suggested the further question as to whether the disease was common to animals in the stable or to animals that were confined to the land.

Mr. OVER said most of the cases he saw were in horses that came from abroad and before the war he had met with it in polo ponies that were imported from the Argentine. He could scarcely recall a single instance in which an English animal was affected.

The HON. SEC., invited to take part in the discussion, said his lack of knowledge prevented him, as he had not come across this disease. However, he would like to thank Mr. De Vine for his most interesting essay. The benefit of the experience of men who had served in France would stand the profession in good stead in the future. He had one or two cases of eye trouble in horses when he had not been able to ascertain exactly what it had been. After ordinary treatment the trouble disappeared, and there had been no recurrence.

Mr. De VINE replying to the discussion, thanked the various speakers for the compliments they had paid him. Although he had read a paper, he hoped they would not think he was posing as an expert. He was really a great deal in the dark about this disease, and it was only recently that he got any information at all about the pathology of it. The bacillus which had been discovered by Dalling seemed to make a choice of settling on the optic nerve; at least, that was where Dalling had found it in most cases. Although only one eye might be affected at the time, the usual result was permanent blindness, and undoubtedly the bacillus spread along the nerve from one eye to the other. Extirpation of the eye might, of course, be attempted, to prevent the trouble spreading to the eye that was sound. The nerve bacillus had been found just immediately in the optic nerve behind the eye. Dr. Dor, who was alleged to have found the bacillus in the vitreous humour, maintained that it required an acid media to live in, and that when an alkaline media formed the trouble cleared up. Dr. Dor was the only authority he had come across who mentioned anything of that kind. A great number of authorities had attempted to discover organisms in discharges from the eye, but nothing specific. Mr. Heelis said he found the trouble as common in mules as in horses. He could quite believe that, because Mr. Heelis was with the cavalry; they generally had British horses which, as they all knew, were the best riding horses in the world and therefore the cavalry got a less percentage of horses of foreign breed than other units. Personally, he saw very little ophthalmia in mules, although he certainly saw some. Most of the cases he saw were in horses imported from America. The cavalry moved about from place to place and were not on lines occupied by horses month after month, winter and summer, where the ground became more or less infected. He was at one with Mr. Stevens in the idea that the land might be, and the worst outbreak he came across was on the Somme, where horses had occupied the same ground months on end. He had seen several cases of isolated

ophthalmia in units; that was, where a case existed and the next one broke out 10 or 20 horses down the line, instead of next to it. He certainly believed the ground had something to do with it, but he could not say definitely. As to whether damping the food was a good thing, as one speaker had suggested, it was well to remember that dry food contained a lot of dust, which might be disturbed by the horse blowing on it and the eye become affected in that way. He did not think food could cause the trouble in any other way.

He had seen a good deal of ophthalmia due to gas. In such cases the lips were swollen and there was ulceration of the mucous membrane of the eyelid, a lot of the gassed animals died of suffocation due to the swelling in the passages caused by the gas. But those animals that lived suffered from no apparent permanent after effects. In treatment he noticed that Mr. Brooke pinned his faith to calomel. It might be a very good thing in certain conditions, but when one gave a thing in powder, one could not give a definite dose. Mr. Brooke was an authority in the treatment of dogs, and he accepted his statement that calomel had answered with them, but with a horse it was different. His experience was that if he blew something into a horse's eye he could not handle the head afterwards to put a bridle on. When they knew that a disease was due to any organism, whether introduced through the food or off the soil, he thought isolation was a good thing. Though the disease may not spread directly, isolation stopped it by means of a carrier. As to whether any cases had been found among horses in this country that had come back from France, he must answer in the affirmative. He had seen several such himself. He thought it was quite on the cards that they would have some ophthalmia to deal with before very long, especially where animals were crowded on the soil. He could not say whether horses were chiefly affected in stables or in the open. In France practically all the horses were in the open, or at least only under sheds.

A hearty vote of thanks was passed to Mr. De Vine for his paper, on the motion of the President, seconded by the Hon. Sec.

The members then adjourned for tea before separating.

H. J. DAWES, F.R.C.V.S., Hon. Sec

#### DUMFRIES AND GALLOWAY VETERINARY MEDICAL SOCIETY.

A meeting was held in the Crown Hotel, Castle Douglas, on June 2nd, of the veterinary surgeons in Dumfries and Galloway counties.

*Present*—Messrs Lindsay and Baird, Dumfries; Milligan and McKenzie, Annan; A. Edgar, Whitburn; Allan and Waddell, Castle Douglas; Nicholson and MacAlister, Kirkcubright.

Apologies were read from—Messrs MacConnell, Wigtown; McKinlay, Stranvaer; Pollock, Lockerbie; Dunlop and Lattler, Thornhill.

Mr. JAS. LINDSAY proposed that a Society be formed of the professional members in Galloway and Dumfries, the Society to be called the "Dumfries and Galloway Veterinary Medical Society."

Mr. MILLIGAN seconded, and the motion was unanimously agreed to.

Mr. EDGAR proposed that Mr. MacConnell, Wigtown, be elected the first President of the Society.

Mr. Edgar said that Mr. MacConnell was one of the best known and respected men in the profession, and he had no doubt that if Mr. MacConnell would accept, the success of the Society would be assured. Mr. MILLIGAN seconded.

Several of the members present hoped that Mr. MacConnell would accept.

Mr. MILLIGAN proposed Mr. Lindsay as Vice-President; seconded by Mr. Edgar. This was unanimously agreed to.

Mr. MACALISTER was elected Secretary and Treasurer. *Subscription.* On the motion of Mr. Baird, seconded by Mr. Edgar, the entrance fee was fixed at £1 1s., and yearly subscription at 10/6.

Mr. LINDSAY took the chair, and said that as the meeting was called to discuss and adopt a minimum scale of fees for the district, they would proceed to discuss same.

The fees adopted are similar to those fixed by the Glasgow Committee, with a few alterations:—

Mileage 1/6, instead of 1/3; Night visits 8 p.m. to 6 a.m. double fees. Parturition: minimum £1 1s.; Milk fever injection 5/-. Examination for Insurance Companies: rates fixed by the National V. M. Association.

The meeting terminated after a lengthy discussion.

NEIL H. MACALISTER,  
Hon. Sec.

#### THANKS TO ELECTORS.

Dear Sir.—As one of the two new members of the Council will you kindly permit me through the medium of your journal to thank those Fellows and Members of the Royal College of Veterinary Surgeons who so kindly voted in my favour.

Evidently the profession is in favour of a progressive policy, and it will be my constant endeavour to watch the interests of the members and merit their confidence.

Yours faithfully,  
G. P. MALE.

#### THE STATUS OF THE PROFESSION.

Dear Sir,—Permit me to offer an apology re some remarks of mine which appeared in *The Record* relative to this subject, where I questioned the courage of Public School-boys. It was really a case of my being unfortunate in expressing myself, as the courage of our Public School-boys as shown in the late war will remain a monument for all time.

What I should have said was, "In how many Public School-boys would be found the natural instinct to become successful Veterinary Surgeons." I offer no apology for this expression, for I am of opinion that the Veterinary Surgeon is a good deal like the poet, "born, not made."

"Watchman's" observations on our "low-grade profession" are in my opinion likely to do more harm than good, especially to our younger members. To the older members like myself it does not matter so much, as we are in a better position to take measurements.

From "Watchman's" style of writing, which is good, he would have shone as a journalist; and this reminds me that in no profession is the "square man in the round hole" deserving of greater sympathy than in the Veterinary.—I am yours, etc.,

The Gables, Reigate,  
Surrey, June 16. CHAS. A. SQUAIR.

#### UNDIAGNOSED—AN ENQUIRY.

To the Editor of the *Veterinary Record*.

Dear Sir,—I shall be very glad if any of your readers will help me with suggestions on the following case:—

The subject is a nine year old cart horse, and the symptoms are absolutely identical with stringhalt, except that the spasmodic flexion of the leg is shown

principally when the animal is standing in the stable, or when resting for a time while at work. The symptoms usually pass off entirely after the horse has walked 10 or 20 yards. He has been known to gallop freely about a field a few minutes after leaving the stable so badly affected that he almost fell over when first moved.

The symptoms have been coming on gradually for about two years, but are now so acute that the animal is rapidly losing condition, and will soon be useless if nothing is done.

I notice that Möller recommends dividing the peroneous tendon below the hock for stringhalt. Have any of your readers had any success with this operation? And would it be advisable in this case?

I shall be very grateful for any helpful suggestions.

Yours faithfully,

228 High Street, Berkhamsted. A. C. WILSON.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919:—

Adamson, D., Bolton	£1 1 0
Adamson, J., M.C., Capt. R.A.V.C.	1 1 0
Cattell, A. J., Brecon	1 1 0
Davenport, C., Capt. R.A.V.C.	1 1 0
Dobbing, W. Newton, Darlington	1 1 0
Fowle, Warwick, Birkenhead	1 1 0
Hoddinott, D. R. F., Evesham	1 1 0
Holland, J., Athy	1 1 0
Howard, C. W., Dorking	1 1 0
Jarvie, T. R., Gateshead-on-Tyne	1 1 0
Linton, R. G., Edinburgh	1 1 0
Powley, J. O., Birmingham	1 1 0
Senior, J. W., Wem.	2 2 0
Sherriff, W., Capt. R.A.V.C.	1 1 0
Taylor, C., Capt. R.A.V.C., 1918-19	2 2 0
Thomas, F. W. H., Major R.A.V.C.	1 1 0
Previously acknowledged	844 12 10

June 17. £863 10 10

#### ANGLO-FRANCO-BELGIAN VETERINARY RELIEF FUND 10 Red Lion Square, W.C. 1.

The following Donations are gratefully acknowledged:—

R. M. Bamford, Capt. R.A.V.C.	£1 1 0
W. B. Edwards, Lt.-Col. R.A.V.C.	5 5 0
J. S. Lloyd, Sheffield	1 1 0
H. A. MacCormack, London	1 1 0
A. Smith, Lt.-Col. I.C.V.D.	1 1 0
C. A. Squair, Reigate	1 1 0
Previously acknowledged	251 9 7

June 17. £261 19 7

#### OBITUARY.

ALFRED MARSTON, Sarmiento, Buenos Aires.

Graduated Edin: May, 1895.

Died 1st June.

EDWARD PERRY, Ibstock, Leics.

1865, Edin: Jan. 1890

Died 1st June, aged 83.

## ARMY VETERINARY SERVICE

Buckingham Palace, June 12.

The King held an investiture in the quadrangle of Buckingham Palace, at 11 o'clock.

The following were severally introduced into the presence of His Majesty, when the King invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted:—

## THE DISTINGUISHED SERVICE ORDER.

\* \* \*  
Captain HARRY POWELL.

His Majesty then conferred decorations as follows:—

## THE MILITARY CROSS.

\* \* \*  
Captain JOSEPH LAURIE.

## MENTIONED IN DISPATCHES.

Appended is the completion of the dispatch received by the Secretary of State for War from General F. R. Earl of Cavan, K.P., K.C.B., M.V.O., Commander-in-Chief of the British Forces in Italy, dated January 18, 1919:—

\* \* \*  
Braid, T.Capt. P. Carroll, T.Capt. P. A., 35th Mob. Vet. Sec. Knowles, Capt. R. H. Little, T. Capt. E., 1st Vet. Hosp. Little, T.Capt. R. J., 22nd Vet. Hosp. Little, T.Capt. W. L., F.R.C.V.S.

The following dispatch has been received by the Secretary of State for War:—

Pretoria, January 20, 1919.

Sir,—I have the honour to forward herewith my recommendations in favour of the under-mentioned Officers, Ladies, Warrant Officers, Non-commissioned Officers and Men for valuable services rendered during the period 1st August, 1918, to the conclusion of hostilities.

I have the honour to be, Sir,  
Your obedient Servant,  
J. L. VAN DEVENTER,  
Lieutenant-General, Commander-in-Chief,  
East African Force.

\* \* \*  
JARVIS, Capt. E. M., M.C., S.A.V.C.; McNAB, Capt. A., S.A.V.C.

The Secretary of State for War has received the following dispatch:—

General Headquarters,  
Mesopotamian Expeditionary Force,  
7th February, 1919.

Sir,—With reference to paragraph 39 of my dispatch dated 1st Feb., 1919, I have the honour to submit herewith a list names of those officers serving, or who have served, under my command, whose distinguished and gallant services and devotion to duty I consider deserving of special mention.

I have the honour to be, Sir,  
Your obedient Servant,  
W. R. MARSHALL,  
Lieut.-General Commanding-in-Chief,  
Mesopotamian Expeditionary Force.

\* \* \*  
Williams, Lt.-Col. (T.Brig.-Gen.), G. M., C.M.G., (Staff).  
Bell, T.Capt. J. Chadwick, Capt. (A/Maj.) C. R. (T.F.).  
Dier, T.Capt. H.V. Lawrence, Capt. C. J. R. Nicholl,  
Capt. (A/Maj.) E. McK. Reynolds, T.Capt. (A/Maj.)  
E. C. Thomson, Capt. (A/Maj.) J. H. (T.F.) Thwaytes,  
Capt. (A/Maj.) R. C. G. Williams, Maj. (A/Lt.-Col.)  
A. J., D.S.O., F.R.C.V.S. Wood, Maj. and Bt. Lt.-Col.  
(A/Col.) W. A.

The names of the following have been brought to the notice of the Secretary of State for War by Maj.-Gen. W. F. IRONSIDE, C.M.G., D.S.O., Commanding-in-Chief Northern Russia Expeditionary Force, for valuable and distinguished services rendered in connexion with the operations at Archangel:—

\* \* \*  
Barnett, Capt. G., M.C., R.A.V.C.

The following despatch has been received by the Secretary of State for War:—

Headquarters,  
Egyptian Army and Sudan Government,  
Khartoum, 26th Jan., 1919.

Sir,—I have the honour to forward herewith the names of officers, officials and others whose work in connexion with military operations, and the situation in the Sudan created by the War, is deserving of special notice and commendation.

I have the honour to be, Sir,  
Your obedient servant,  
LEE STACK, Major-General,  
Acting Sirdar of the Egyptian Army and  
Acting Governor-General of the Sudan.

\* \* \*  
Soutar, Cap. J. J. M., R.A.V.C. Tapley, Maj. and Bt. Lt.-Col. J. J. B., D.S.O., R.A.V.C.

The following Despatch has been received by the Secretary of State for War:—

General Headquarters,  
5th March, 1919.

Sir,—I have the honour to forward herewith a list of officers, Nurses, other ranks and civilians, whom I consider worthy of mention for their services during the period from September 19, 1918, to January 31st, 1919.

I have the honour to be, Sir,  
Your obedient Servant,  
E. H. H. ALLENBY, General,  
Commander-in-Chief,  
Egyptian Expeditionary Force.

\* \* \*  
STAFF: Bartrum, Capt. (T.Maj.) V.A., O.B.E., R.A.V.C. (T.F.). Beatty, Maj. P. V., R.A.V.C. Butler, Col. (T.Brig.-Gen.) E. R. C., C.B., C.M.G., F.R.C.V.S., R.A.V.C. Fail, Maj. (A/Lt.-Col.) F. R.A.V.C. Lloyd, Capt. (T.Maj.) G., D.S.O., R.A.V.C. (S.R.). Nicholas, Maj. (T.Lt.-Col.) J., R.A.V.C. Grey, T.Capt. G. O. R. Hollis, T.Qrmmr. and Lt. W. Martin, T.Capt. T. D. M. Maynard, T.Capt. F. O. Morrow, T.Capt. J. J. Waters, T.Capt. W. Whitehead, T.Capt. G. Williams, Capt. H. B. (S.R.).  
Aitken, Capt. W. (T.F.). Cunningham, Capt. J. (T.F.). McIntyre, Capt. (T.Major) P. (T.F.). Palmer, Capt. (A/Major) R. B., M.C. (T.F.).  
Murray-Jones, Major F., A.A.V.C. Worthington, Major H., A.A.V.C.

Extracts from *London Gazette*

WAR OFFICE, WHITEHALL, June 5.

## REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

The follg. temp. Capts. relinquish their comms. (June 6), and retain the rank of Capt. :—P. J. Sheil, on account of ill-health contracted on active service; A. A. Hayman, on acct. of ill-health caused by wounds.  
Capt. J. M. Richardson, T.F., to be actg. Maj. whilst holding the appt. of D.A.D.V.S. (Feb. 24).

June 6.

Temp. Capt. R. K. Porteous relinquishes his comm. on acct. of ill-health (June 7), and retains the rank of Capt.  
C.A.V.C.—Temp. Lt. O. V. Gunning to be temp. Capt. (April 29).

June 7.

Temp. Capt. N. Wright relinquishes his commn. on acct. of ill-health (Apr. 6), and retains the rank of Capt. Temp. Qrmr. and Lt. F. Benwell, D.C.M., R.A.V.C., to be Capt. under Art. 330, R. Wt. for Pay and Promotion (June 1).

June 12.

Temp. Capt. W. P. B. Beal relinquishes actg. rank of Maj. on ceasing to hold appt. of D.A.D.V.S. (Mar. 16), (substd. for notification in *Gazette* April 25).

The surname of Temp. Capt. D. S. Rabagliati is as now described, and not Rabagliati, as in *Gazette* Feb. 5.

Temp. Capt. P. MacLaughlin relinquishes his commn. on acct. of ill-health contracted on active service (June 13), and retains rank of Capt.

S. Afr. Vet. Corps—Temp. Capt. S. Elley resigns his commn. (Dec. 3, 1918), and retains the rank of Capt. (substituted for *Gazette* notification Feb. 17, 1917).

June 13.

Temp. Lt. S. Holmes to be temp. Capt. (May 9).

June 14.

Capt. P. J. Malone relinquishes the actg. rank of Maj. (April 16); Temp. Lt. F. W. Thompson to be temp. Capt. (April 22).

June 17.

Capt. H. C. Jagger, O.B.E., T.F., relinquishes the actg. rank of Lt.-Col. on ceasing to hold the appt. of A.D.V.S. (April 1). The following Capts. relinquish the acting rank of Maj.:—On ceasing to hold the appt. of A.D.V.S.:—R. H. C. Higgins (Dec. 2, 1918); E. McK. Nicholl (Dec. 7, 1918); R. C. G. Thwaytes (Dec. 20, 1918); H. Peele, T.F., on ceasing to hold the appt. of D.A.D.V.S. (March 23); F. Hopkin, T.F. (May 13).

Temp. Lts. to be temp. Capts.:—O. McGuirk (May 18); S. G. McKee, L. Senecal (May 22); W. S. Grogan (May 28).

TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

June 7.

Capt. (actg. Maj.) J. R. McCall relinquishes the actg. rank of Maj. on ceasing to be empld. (May 8).

June 11.

Capt. D. R. C. Tennant, F.R.C.V.S., to be Maj. (May 11).

RESERVE.

June 14.

Capt. J. M. Magill, from R.A.V.C., to be Capt. (June 15).

### The "law" of supply and demand.

The following is from the editorial page of the current copy of *The Meat Trades Journal*.

"We recently called attention to the indiscriminate slaughter of calves that was taking place under Control, and pointed out how serious it was for the future of the meat industry. With de-control the prices paid by retail traders have more than doubled, and this adds one more danger to our supply, for if breeders and feeders can realise 2s. per lb. for them, the temptation to sell is too big a test, and the last state of our herds will be even worse than we anticipated. It is idle to blame the farmer and talk about his greed, etc. It is the butchers' fault, for they make the price, to the entire satisfaction of the seller. Will we as a trade never learn?"

The following intimation appears in the daily press of June 20:—

"Calves, which ought to have been kept for rearing, have been sold in large quantities for slaughter. This has given grave concern to the Board of Agriculture, and the Food Controller, after very careful consideration, and with the concurrence of the Board of Agricul-

ture, has re-imposed maximum retail prices for veal. These prices will, until further notice, be the same as those in force up to May 31. The new Order, which does not apply to Ireland, will come into force on Monday.

### REGISTRATION TO CONTINUE.

As a result of the recent drought and its detrimental effect on the fattening of livestock, there is a danger of the amount of meat available for consumption being restricted, and the Food Ministry has accordingly decided that the registration of customers with retailers for butcher's meat, which it had been hoped to abolish on June 30th must continue."

At the sale of Lord Rayleigh's Friesian cattle, the bull "Levenham Janus," 2½ years, made 3600 guineas, and a cow, "Jeltie," six years old, 5300 guineas. Eighty animals realised 22090 guineas.

### Claim for value of a Horse.

#### Kicked, or struck by Lightning?

At the Carnarvonshire Assizes on Tuesday, Mr. Justice Avory and Jury heard an action brought by Evan Thomas, farmer, "Tan-y-dderwen," Llanddeiniol, against Grace Roberts, "Braich Kiffri," in the same parish, claiming £150, being the value of a horse alleged to have been killed by a ferocious stallion which had trespassed from the defendant's land on to the plaintiff's land.

Mr. Artemus Jones, K.C., and Mr. T. E. Morris (instructed by Mr. Richard Roberts) appeared for the plaintiff, and Sir Ellis Griffith, K.C., and Mr. Austin Jones (instructed by Mr. Thornton Jones) for the defendant.

The plaintiff, Evan Thomas, said he had been offered £150 for the horse. He was all right the night before. He had offered to settle with the defendant, but she refused, because Mr. Trevor Williams had told her that the gelding had died as the result of lightning going up its nostril and fracturing the skull.

Richard Thomas, son of the plaintiff, said he turned the horse into the field on the night of the 11th Sept., and it was alright when he saw it at 11.30 that night. Early the following morning he saw a stallion in the field, and some distance away was their horse lying dead.

Cross-examined: Witness said that he did not hear any thunder nor did he see any lightning the previous night after he turned the horse into the field.

Mr. L. W. Wynn Lloyd, M.R.C.V.S., Carnarvon, said when he examined the horse he saw thirteen marks on the horse's side, and they appeared to him to be bite marks and there were five or six marks on the other side. He made a post-mortem examination and found all the organs healthy. He then decided to defer the remainder of his examination until the following day, and get a knacker to skin the horse, and then examine the skull and spinal cord. When he got home he phoned to Mr. Trevor Williams to ask him to meet him the following day to complete the examination, as he wanted to do justice to both parties. The following day Mr. Trevor Williams, instead of meeting him at the plaintiff's farm, went to defendant's farm. After waiting a while he went to defendant's place and found Mr. Williams examining the stallion. On the way to plaintiff's farm Mr. Williams said "No doubt this horse was killed by lightning." They both proceeded with the post-mortem. The head was skinned. There was a fracture of the skull, and Mr. Trevor Williams agreed that that was the cause of death. It was a depressed fracture, and there was a good deal of congestion of the parts immediately under it. There would be

less likelihood of hæmorrhage because death was instantaneous.

Cross-examined by Sir Ellis Griffith : After seeing the dead horse he telephoned to Mr. Trevor Williams at Llangefni, as he could not make out the cause of death at the time. He (Mr. Lloyd) ultimately came to the conclusion that the horse died from shock following concussion. He was of opinion that the blow could not have been inflicted after the horse's death. The marks on the horse were bites.

Mr. R. Jones, M.R.C.V.S., Towyn, Merioneth, said he saw the dead horse on September 15th, 1918. He found teeth marks on the skin. He was of opinion that death was due to shock caused by fracture.

Cross-examined, witness admitted that the blow might have been inflicted either by a horse or through human agency. There were thirteen marks on one side of the horse and six on the other. In his opinion lightning was an impossible cause of death. If the horse had been struck by lightning decomposition would have set in at once. He never saw a case of this kind before.

Mr. David Evans, M.R.C.V.S., Llanrwst, corroborated the two last witnesses.

J. Morris Williams, a neighbouring farmer, said he valued the dead horse at £150.

R. Jones said he lived near the plaintiff's and defendant's farms. He was also of opinion that the horse was worth about £150.

Dr. Taylor Jones, Professor of Physics at the Bangor University College, said lightning might cause fracture, but in that case it would leave a mark on the skin. If lightning had gone up one nostril and came out through the other, it would have left a mark.

#### THE DEFENCE.

Sir Ellis Griffith for the Defence, said that there was a violent thunder storm on the night the horse was killed. Mr. Wynn Lloyd went to the defendant's house but never said a word about the horse having been killed as the result of a kick. Mr. Lloyd made notes at the time but those notes could not now be found. They ought to have been in the possession of the solicitor for plaintiff. There was no mention of horse bites in those notes from beginning to end. Mr. Lloyd had a consultation with Mr. Trevor Williams. The latter suggested that the horse had been killed by lightning.

Miss Grace Roberts, the Defendant, said the Plaintiff came to her about the dead horse. He said her stallion had killed his horse, and he was not going to stand the loss. There was a heavy thunder storm the previous night and she suggested that Mr. Wynn Lloyd should examine the dead horse to ascertain the cause of death. When Mr. Lloyd saw it, he said that fever or illness was not the cause of death, and that it might perhaps take a month to ascertain the cause.

Cross-examined: Witness said that if Mr. Lloyd said her stallion killed defendant's horse, she would cover the loss.

John Jones, Bailiff at the defendant's farm, said there was a heavy thunder storm on the night the horse was killed.

C. J. Rawles, Electrician in the employ of the L. & N. W. Ry. Co., said he was called to duty at Pontrythall Station on the night in question on account of the thunder storm having caused the wires to fuse.

Griffith Jones "Wern Fawr" Llanddeiniol said he saw no teeth marks on the dead horse.

Cross-examined: Witness admitted there had been complaints concerning the viciousness of the stallion. His mare had been bitten by him once.

William Parry who was at the time a farm servant in the employ of defendant, said he came in late on the

evening the horse was killed. It was raining hard at the time, and on account of the storm he had to dismount from his bicycle.

Mr. Trevor Williams, M.R.C.V.S., Llangefni, said Mr. Wynn Lloyd consulted him as to the death of the plaintiff's horse. He suggested to Mr. Lloyd that it might have been a flash of lightning that killed the horse. He was the first to notice the depression on the dead animal's forehead. The skin had been removed by then. He saw no trace of nasal hæmorrhage. It was that same day (at the Assize) he first heard of horse bites. He saw three cattle which had been killed by lightning some time ago at Llanfechell. There were no marks at all on two of them. The latter might have been in the open fields at the time. There was a thunder storm on the night in question.

By the Judge: He was of opinion that the stallion could not have kicked the horse on the forehead unless someone held it down.

The Judge: You are not to answer my question in that flippant manner. I asked a scientific question to a scientific man.

Witness (continuing) was of opinion that a fracture by a direct blow was impossible only through the agency of lightning. The dead horse had an enlarged heart.

The case was adjourned until Wednesday.

On Wednesday morning Mr. Trevor Williams said that it was lightning in his opinion that had killed the horse.

Mr. Hugh Williams, M.R.C.V.S., Ty Croes, said he saw the dead horse. It had been skinned by then. It had an enlarged heart. He saw no signs of a horse having crossed the ditch from one field to another. He agreed that death might have been caused by lightning. If it had received a blow on its head there would have been hæmorrhage. The fracture might have been caused after death.

By His Lordship: The parts immediately under the fracture contain no blood vessels but are very vascular.

Mr. John Matthews, M.R.C.V.S., Anglesey, thought it was very improbable that the horse had been kicked on the head.

By His Lordship: Shock caused the concussion and fractured the skull.

Do animals suffer from shock? I cannot answer your Lordship.

Mr. R. M. Malloch, M.R.C.V.S. (Retired) of Kirkby Stephen, said he had made a special study of animals that had been killed by lightning. He had written a book on the subject but it could not be printed now owing to shortage of paper. He had seen a great number of animals which had been killed by lightning. Many had marks on them and others were without marks. He believed the horse in question was killed by lightning. He did not agree that immediate decomposition followed death by lightning.

Mr. W. Griffith Williams, Architect, Bangor, said he visited the fields in question and produced a plan which he had made of the spot where it was alleged the stallion had crossed from one field to another. The wire-netting had been clean cut by an instrument.

The Plaintiff, recalled, said it was quite untrue that the wire had been cut by him or by his instructions.

After Sir Ellis Griffith and Mr. Artemus Jones had addressed the Jury, the Judge summed up, and said that a good deal had been said as to how the stallion got into plaintiff's field. It matters nothing how he got there if in fact he was there, which fact was not disputed. If then he was there, he was trespassing. The Jury had heard the evidence of Mr. Wynn Lloyd, which was consistent and straightforward, and though he was subjected to very severe cross-examination by Sir Ellis Griffith,

he never wavered. A good deal had been made of the fact that Mr. Wynn Lloyd had not designated the marks on the skin "bite marks" in his original notes. This, as a matter of fact, shewed to him (His Lordship) that he was impartial. Mr. O. T. Williams, on the other hand, repeatedly contradicted himself on material points. He first said that the fracture of the skull had nothing to do with the death of the horse. Then he said that the fracture was caused in a miraculous way by lightning, and further, he suggested that it was done after the death of the animal. He again maintained that the stallion could not strike a direct blow with his fore foot on the horse's forehead which is perpendicular. A good deal was made of this point by the learned Counsel for the Defence. What in fact is the position of the horse's head when the animal is at liberty? It is never perpendicular except when held in that position by a bearing-rein. The position at liberty assumes a forward slope from the forehead towards the nose. In this position it can be readily understood that a direct blow could be inflicted by the stallion's fore foot. To deny this shewed to him that Mr. Williams was ignorant of the rudiments of dynamics. Mr. Williams swore that the stallion was not capable of rearing in order to strike the horse, but it was proved that he had done his duty as a sire that season. Mr. Trevor Williams said that the gelding had an enlarged heart but this was not corroborated by the other witnesses. Science may carry one too far. Let me give you an illustration. A man is found dead with a bullet wound through the head. The assassin is found standing by with a revolver in his hand. Half-a-dozen doctors are called to prove that the dead man had a diseased heart and that the very sight of a

pistol pointed at him would be sufficient to cause him to fall down dead. Could any Jury be found foolish enough to say that the assailant was not guilty of murder? The expert evidence for the Defence was speculative. It was claimed that the horse must have been struck by lightning though the witnesses for the Defence admitted in cross-examination that the usual signs were absent, except that the carcass had decomposed four days after death. This statement even was emphatically denied by expert witnesses for the plaintiff. Mr. Williams admitted there were a few marks on both sides of the dead horse. He thought they were caused by the horse falling dead in the field. Now the horse could not have fallen on both sides.

The Jury, after consultation, returned a verdict for the plaintiff for the full amount of £150 and costs.

His Lordship gave judgement for this amount with costs.

#### Charge of cruelty at Greenwich: "Cast" Army Horse.

During the hearing of a charge at Greenwich Police Court on Tuesday, 17th inst. of working a horse in an unfit state, Mr. M. G. Byerley, F.R.C.V.S., said the animal was branded with a "C," which indicated that it was an Army "cast" horse, and so was useless.

Mr. Hay Halkett (the magistrate):—Then why does the Government sell it and so encourage cruelty?

Mr. Byerley said the public were misled into supposing that these horses were useful, and it was a practice which was both cruel and cowardly. The Remount Department was responsible.—*The Times*.

JUNE 28, 1919.

VOL. XXXI.

## PROFESSIONAL ORGANISATION.

The present position and needs of the profession have been discussed briskly for some months past; and some accord has been reached on at least two points. It is generally agreed that veterinary surgeons are too "apathetic," and there is a further recognition of a need for professional organisation and combination. The former is an old and just complaint; and if it could be remedied, organisation and combination would be a simple matter. A few men have already provided us with excellent machinery for organisation and combination; the problem to-day is to induce our members to make use of it.

We have an internal political constitution which, from its arrangements empowering us to manage our own affairs by a Council of our own election annually susceptible to our influence, may fairly be called an ideal scheme of self-government. Doubtless it has often worked unsatisfactorily; but, when it has done so, the fault has been in the men working it, not in the system. It has always been difficult to focus the attention of the electorate upon a test question sufficiently closely to get a straight vote on it; and many a practitioner to-day is so far from appreciating his right of annually voting for a quarter of the Council that he is attracted by the idea of limiting his vote to one or two members to represent his own district. The only thing to be said against our political constitution is that so far it has been too good for us. The profession as a whole has never learned how to use it.

A more recently created but equally admirable machine for dealing with practically all professional matters not governed by the Council is the "National" with its affiliated local branches. In its present form it became available so shortly before the war that we have not yet had the chance of making real use of it. The chance is coming now, but are we likely to take it? One essential to the effective use of the "National" is that its local branches should be well manned by members, and that those members generally should take an active interest in both local branch and central body. At present, many members are outside all professional associations, and many of those who do join one take only very slight interest in it. The profession must break with one of the worst of its old traditions before the "National" can become the power for good it might be.

Speaking broadly, veterinary surgeons have not yet learned to think collectively. Machinery for collective deliberation and action as good as that possessed by any profession lies ready to their hands, and most of them never think of using it. The present need seems to be for an educative propaganda within the profession.

## NOTES ON

### A GERMAN VETERINARY HOSPITAL.

I met recently a farmer's son who is an N. D. A. of the Harris Institute, Preston, who had been a prisoner of war in Germany for twelve months, and this account was given to me by him.

When he first joined the army he was in the R.A.V.C. but being a class "A" man was transferred to the infantry, and whilst with them he was taken prisoner.

Amongst his occupations whilst in their hands he was attached to a German Veterinary Hospital at Tournai, Belgium. This hospital was in the Cavalry Barracks of that town, and although he was somewhat restricted in his movements about the place, he reckoned that it had accommodation for about 600 animals. The major part of the work was done by Belgian civilians: very few Germans were employed, except the staff—the guards and the N.C.Os.

The English prisoners varied from 15 to 50, and were mostly employed in the Remounts Transport stables. The stable routine was as follows:—First feed, 6 to 7 a.m. and comprised both corn and hay. The stables were provided with hay racks but these were not used, as the hay was thrown on the floor. 8 a.m. water, afterwards grooming. 11 a.m. corn feed. 2 p.m. water and then exercise. 5 p.m. corn, hay, water; and that concluded the day's routine.

The three corn feeds consisted of a mixture of tailed wheat, rye, and crushed maize 2lb. Dried vegetables (chiefly swedes)  $\frac{1}{2}$ lb. made up with chaff, which was mostly straw soaked in molasses? The dried vegetables, unless previously soaked in water, (two handfuls to a bucketful of water) had a tendency to cause colic, the treatment of which consisted of a drink and then a run round the yard.

A compressed food which was brought to the hospital in half-cwt. paper bags, was also used; it appeared to be oats and rye—probably the screenings from the flour mills. The hay varied greatly in quality; sometimes it was very good and at other times very bad. The bedding was peat-moss litter and there appeared to be no restrictions as to the quantity used.

This particular soldier often assisted in the operating theatre in the casting of the animals, and said the building was a large one and very well equipped. There was a Dollar's operating table with a padded side, but most of the cases were cast with hobbles. There was not much chloroform used—mostly cocaine; but when used it was poured on to a pad of *papier-maché*—this being their substitute for cotton wool—and this was placed in the bottom of an iron stable bucket. The latter was then slipped over the horse's mouth and nostrils, including both jaws, then a blanket covered the horse's head.

There were three veterinary officers at this hospital, but most of the operating was done by a young surgeon. For fistulous withers his favourite treatment was setoning. An operation at which this soldier assisted was that of nymphomania in a mare. A stallion and this mare were both cast at the same time and a freshly extracted testicle from the stallion was sewn into a wound made in the mare's neck. This was left there for about ten days and then removed. The wound in the neck took about a month to heal; and the soldier informs me that the mare was afterwards discharged cured.

In June and July, 1918, many castrations of Belgian stallions took place. The instrument used was the emasculator. They were all cast, but no chloroform was used, and one morning he assisted in the throwing of 14 animals.

For laminitis he saw tried a shoe one inch thick which covered all the foot except the frog, but he says it had no effect on the animals.

Belgian civilians did most of the wound dressing, and the standard dressing used was known as "goat" and which had the colour of an indelible pencil.

In dressing wounds very little water was used. There were very few mules in that hospital and those they had were captured from us.

Skin cases were washed in a weak solution of disinfectant somewhat resembling our coal-tar preparations.

The operation for nymphomania appears to be quite unique as I cannot find any such thing suggested in the English and American text books on surgery. I fail too see how it can have any desired effect on the mare. Also the wound in the neck took a month to heal, which is a consideration when mares can be fit to work in a week after the ordinary operation of "spaying."

G. C. LANCASTER, F.R.C.V.S.

Burnley, Lancs.

#### LINCOLNSHIRE AND DISTRICT VETERINARY MEDICAL SOCIETY. [NATIONAL V.M.A.—SOUTHERN BRANCH.]

The Annual Meeting was held at the Angel Hotel, Peterborough, on Thursday, June 12th. The President, Mr. C. W. Townsend, F.R.C.V.S., Long Stanton, in the chair; there were also present Mr. H. H. Truman, March, Vice-President; Messrs. T. B. Bindloss, Long Sutton; F. L. Gooch, Stamford; R. W. Knowles, Wisbech; G. Lockwood, Peterborough; A. Lennox, Crowland; H. H. Nicholls, Oundle; J. H. Poles, Whittlesey; T. A. Rudkin, Grantham; E. Porter-Smith, Lincoln; with Mr. T. Hicks, Sleaford, Hon. Sec. and Treasurer.

The Secretary read several letters of apology. Mr. Trevor Spencer wrote that he could not attend but he hoped they would renew their kind invitation to the next meeting at Peterborough. Similar apologies were received from Mr. W. W. Grasby, Daventry and Mr. T. Holmes, Bourne, (Vice-Presidents), and Mr. T. J. Keall, Gainsborough.

#### DELEGATES TO CONGRESS OF SANITARY INSTITUTE.

An invitation was received to send delegates from the Society to the Congress of the Sanitary Institute at

Newcastle. The President and Secretary were nominated, and eventually it was agreed to leave the matter to the them as to which should attend.

Later in the meeting Mr. Gooch emphasised the importance of the Society being represented, and said he should be present in a private capacity. It was understood that in the event of the President and Secretary being unable to go, Mr. Gooch would be able to represent the Society, and that the expenses of the delegates would be paid by the Society.

*Subscriptions.* The SECRETARY suggested that it was not quite right to ask the members to pay their subscriptions for the two years of 1917-18, during which there had been no meetings. A few had already paid, however.

Mr. TRUMAN asked what was the state of the funds.

The SECRETARY said the Society was in a good position as regards its financial aspect. He had £43 in hand.

The CHAIRMAN said even from 1914 to 1916 the meetings, owing to the war, were poorly attended, and that during this period several members had been away on active service.

After some discussion Mr. Truman moved that the fees for the two years 1917-18 be not paid.

Mr. POLES seconded and the resolution was carried.

The PRESIDENT: We pay for 1916 and for 1919 but not for the years 1917-18!

Mr. GOOCH said in some societies no subscriptions were drawn from men during the time they had been serving in the army. Of course some are still serving and not yet returned.

The PRESIDENT: We have a total of 18 members who have served with the A.V.C. during the war.

It was agreed that as all would benefit by the resolution just passed, no further alteration be made.

*Sympathy.* The SECRETARY said he had received a letter from Mr. J. Mackinder of Peterboro' (who had severed his connection in practice) sending in his resignation.

Mr. GOOCH proposed that the Secretary ask Mr. Mackinder to reconsider it. Mr. Truman seconded and the meeting agreed.

Mr. LOCKWOOD said he did not know if the meeting were aware that Mr. Mackinder had recently had the misfortune to lose his wife. He suggested that a letter of sympathy be sent.

The members rose to signify their agreement with the proposal.

The PRESIDENT said unfortunately several members of the Society had died during the last few years. Owing to the Secretary being then away on active service, and no meetings held, the usual letters of sympathy had not been sent in all cases. He proposed that letters of sympathy be sent to the relatives of the following with an explanation as to why they had not been sent before:—Mrs. T. N. Clarke, Newmarket; Mrs. A. R. Routledge, Louth; Mrs. R. W. Clarke, Wragby; Mrs. B. A. Searby, Ramsey.

Mr. RUDKIN seconded, and the resolution was carried, the meeting standing.

*New Member.* Mr. A. S. Leese, of Stamford, was elected a member of the Society on the nomination of Mr. Gooch, seconded by the Secretary.

#### THE PRESIDENTIAL ADDRESS.

Gentlemen, This is the first meeting this Association has held since the conclusion of hostilities, and I can assure those members here to-day, that it is a great pleasure to me to once more have the opportunity of presiding, and being back with you again after a period of nearly five years.

This Association, like many more of the smaller Veterinary Association in this country, reluctantly decided, at the meeting held at Grantham, in February 1916, that

owing to military circumstances and to the fact that many of its members were serving in His Majesty's Forces, it was then practically useless to continue our meetings.

We must congratulate ourselves, for the long looked for peace is now in sight, I think I may say, sooner than some of us at one time anticipated, and this association is now able to resume its usual meetings, I trust with more vigour and keenness than before. The attendances of members in the past has been far from what it ought to be, our meetings are only held three times in the twelve months, I know it is frequently difficult to attend regularly when one is single-handed, as many of us are, but I feel sure that more members could attend if they tried. The district covered by the Association is situated in one of the best and most important agricultural parts of England; we seldom see one another except at our meetings, and surely one of the chief objects of our various associations is to enable veterinary surgeons to meet together, thereby promoting good feeling and fellowship, at the same time discussing our views on veterinary topics and matters pertaining to our own welfare and also those relating to the profession in general.

On looking through the last five years, many changes have occurred. We have all had our troubles to meet, many of us who have been abroad have passed through and experienced many anxious months during what may be described one of the biggest struggles in the world's history. Those of you who for various reasons were compelled to remain at home to "carry on" and look after the interests of stockowners and agriculturists have also undoubtedly had numerous difficulties and hardships to undergo, and many weary months of waiting and wondering when the war would end; gentlemen it has ended, and with the coming of peace, many changes and difficulties confront us. There is not the least doubt that this country is passing through a very serious crisis, and our profession like every other trade and calling will, I feel sure, have innumerable difficulties to face in the near future.

Personally I do not think we as a profession have much to fear. I, unlike many, am not pessimistic. I maintain that our abilities are gradually becoming recognised by the general public; our social status has made considerable improvement in the last few years, and I have every reason to think this will be maintained and upheld. At the same time I consider openings and opportunities present themselves now which will increase our work and recognition in many ways in the near future.

As regards the work done by the A.V.C. during the past war, in my opinion seldom before has our profession had such a splendid opportunity of actually demonstrating to the general public what we can do when given a free hand. In the army we had this opportunity. Our advice upon the health of animals was not only eagerly sought after, but always acted upon, and I consider that throughout the war our corps did most excellent work; it is no doubt owing to them that mortality and animal wastage was always kept so low. Never before have we had so many animals under our care. When one remembers that in peace time the total number of horses in the army was roughly 19,000, whereas at the conclusion of hostilities it approached something like 750,000 animals, and that losses from all causes was under 12%, it gives some idea of the way the horses were looked after, and at the same time does, I maintain, reflect great credit upon the A.V.C. Moreover, judging from the remarks of Maj.-Genl. Birkbeck, Director of Remounts, this branch also appreciated our work, for he states that the veterinary surgeons had established an unexampled veterinary service, and that our preventive hygiene was beyond all criticism; whilst in hospital

installation, aided by the R.S.P.C.A., our work was beyond all praise. Such remarks as these coming from an important Government official can scarcely escape the notice of the general public, who I vouchsafe will not be slow in realising the good work done by our profession during the war. It is also indeed most gratifying to see that His Majesty The King has honoured our profession by granting to the A.V.C. the prefix "Royal," in acknowledgement of good work done by the corps in various theatres of war.

Personally, I think the profession as a whole was most patriotic in joining the army, for we are told that out of a total of 3000 veterinary surgeons in the United Kingdom, over 1200 were employed in the A.V.C. either in a civilian or military capacity. Even our own little association provided 19 out of a total of 48 members. If, therefore, one realises the comparative small numbers of veterinary surgeons serving in the regular A.V.C. in peace time, and compares it with the numbers that assisted in carrying on the tremendous work during the war, one can then see how the civilian veterinary surgeon quickly came to the rescue; and there is not the least doubt that the excellent results obtained were due in no small measure to the valuable help given by many of the elder civilian veterinary surgeons, who willingly left their practices, and assisted in carrying on the work of the A.V.C. I hope that some members of this society who served in the various theatres of war, will at some future time come forward and give us papers on experiences gained, for on account of the large numbers of animals, one had to deal with diseases on a scale that one seldom meets with in private practice.

A disease I would like to see more fully investigated is specific ophthalmia, which, during the last three years of the war was the cause of much blindness, and on account of very little being definitely known until recently as to its cause and treatment, one could not do much in preventing its occurrence. Personally I consider this disease was the cause of greater financial loss than any other met with in France during the war.

Other important questions that confront us at the present time are the old ones of College funds, contagious diseases and research work, Ministry of Public Health Bill, Milk Bill, Present scale of fees, Work of the Council, Animal Anæsthetics Bill, all of which I think you will agree are matters of great importance, I propose to briefly refer to them all, and as we have no paper to be read at this meeting, I do not think we can better occupy our time here to-day than to ask those members present to give us their views and opinions upon some of the items I have just mentioned, all of which have been much discussed in the various veterinary periodicals during the last few months.

With regard to the question of college funds, we all know that our College has had to carry on its work in spite of great financial difficulties for many years past, owing to its main source of income being derived from students' fees. The number of students during the past ten years has gradually decreased until the College is now on the verge of bankruptcy. Surely this state of affairs cannot continue; help must come from somewhere, and the question arises as to where and by what means this help has to come. I maintain that we have been self-supporting long enough, and that it is now the duty of the State to come forward and give us their assistance. At the same time I feel sure that neither the State nor the general public sufficiently realise our true state of affairs, nor do they appreciate the importance and extent of our work. If this is so it behoves each one of us to demonstrate this in every possible way.

In the past the veterinary profession have done excellent work for the agriculturists of this country, in the eradication of contagious diseases, many of which are now non-existent here, owing entirely to our work.

There are several diseases—Contagious abortion, Joint-ill, swine fever, Influenza, Tuberculosis, Helminthiasis, and others I could mention—all of which are still the cause of great annual financial loss to this country, and which afford ample scope for further investigation. The whole question as to whether sufficient research work is being carried on in connection with control and eradication of contagious diseases at present existing in this country has lately been much discussed in our Veterinary Journals, and judging by present statistics I, personally, feel sure that given increased financial assistance—which would mean the employment of more officers, much better results would be obtained, and that the whole country would benefit thereby. Our work has been, and always will be, closely connected with the agricultural industry of this country and when we hear so much of what the Government is going to do for agriculture we can only hope that the important part the Veterinary profession has played in the past will not be lost sight of, and that ample funds will be allocated to us for carrying on work which we are only too willing to do if given sufficient means. It is, I consider, up to every one of us to bring to the notice of prominent agriculturists and public bodies, such as farmers' unions, agricultural committees, even our members of parliament, that the control of contagious disease in animals is due entirely to the work of our profession, and furthermore that, since many of the contagious diseases in animals are directly transmissible to man, it is of the utmost importance that we should be ably and fully represented in all matters connected with public health. I consider that in many instances this is not the case. Meat inspection, I maintain, should be done only by qualified veterinary surgeons; yet at the present time, except in some of the largest towns this is not the case, this subject is a matter that the profession might once again take up. Several years ago this matter was discussed but nothing definite came of it; surely our knowledge of the pathology of animals specially fit us for this work.

With regard to the Ministry of Public Health Bill we are told by the Council that they are fully alive to the importance of the Bill and that in the interests of our profession it is being carefully watched; it is therefore hoped that when this and other legislative measures at present before Parliament become law our profession will obtain proper recognition in all advisory and administrative matters to which our special training entitles us.

Just now there seems to be a lot of needless criticism and grievances with regard to our present Council and the work they have done. Personally, I think one must look upon this as a good sign, for it shows that the profession is taking an interest in matters pertaining to its welfare. The Council, like other public bodies has had to carry on amidst many difficulties; it has also been undoubtedly hampered by lack of funds: this difficulty will, we hope, be overcome when the new Annual Fee Bill comes into force and should be the means of enabling the Council to assist us in many matters which without necessary funds it is unable to do. One knows that the work involved by any public calling is frequently an unenviable task and associated with much comment, but, when one considers the amount of time the doings of the Council involves and the work they have done we have a great deal to be thankful for, and particularly is our present President to be thanked for his energy and splendid work and the great interest displayed at all times in furthering the progress of our profession.

Whether our present system in the selection of members of Council could be improved upon, if election on the Parliamentary plan by splitting up the profession into divisions were adopted, is a question: this might

possibly be a more popular method, but on the other hand the important point is; would it be the means of obtaining better men? Personally I doubt if this would be so. By the present system, each candidate appeals to the whole profession and has the satisfaction of knowing that if elected it is by votes coming from veterinary surgeons all over the Kingdom; this could not be said if district representation were adopted.

An important question that behoves us to carefully consider is the one of a scale of fees, but since this is on the agenda, I will only briefly remark upon it. I think it is impossible to establish a uniform scale of fees throughout the country, as to cover all the requirements of general practice, on account of condition varying so much in different districts. We all realise that a considerable increase in the ordinary fees must be made; and I think that even in general practice a more uniform scale of fees could be adopted. The only way of doing this, so far as I see, is for neighbouring practitioners in any district to confer together and agree mutually among themselves. As regards our fee for work in special branches—Insurance fees, Town Councils, County Councils, it would be much more satisfactory if uniformity could be adopted, it has already been done by many Societies, and it is now up to this Society to do likewise.

There are other matters connected with the future of our profession which one would like to comment upon—Petrol for veterinary surgeons at cost price, Animal Anæsthetics Bill, Compulsory Examination and Registration of Farriers' Bill, The question of whole or part time inspectors for contagious diseases; however, I feel I have taken up quite sufficient of your time to-day. I have endeavoured to give you as shortly as possible some opinion I hold as regards our future prospects. We, as a profession have made much progress, by our united efforts I feel sure this will continue; but I sincerely trust we shall obtain in the near future from the State the assistance we deserve, by which, not only the profession but the country as a whole would be benefitted.

It was decided to defer discussion of items referred to in the President's address, until next meeting, but one or two subjects were touched upon.

Mr. GOOCH said the President had referred to the fact that the A.V.C. had not been given credit by the public for the work they had done. There was a lot said in *The Times* recently about the Remount Department, but no reference to the Veterinary services.

Mr. PORTER-SMITH said the prices made by the horses sold out of the army showed how well they had been kept.

Mr. GOOCH said the question of the College funds came home to everyone. If it were not supported, there soon would not be a College. They ought to try and use their influence to get State help. They had help in Ireland, but not in England. Then in regard to meat and market inspection—how many markets were inspected?

The SECRETARY said that Sleaford market was not.

Mr. GOOCH said there was not one in Kesteven that was.

Mr. PORTER-SMITH: If Sleaford were inspected it would not be passed.

Mr. RUDKIN: I inspect Grantham market.

Mr. GOOCH said he only referred to County markets, not Boroughs. The Society of Meat Inspectors was holding a meeting at Newcastle, and that also should be supported. The work of inspection should be in the hands of veterinary surgeons. At the present time it was in the hands of doctors or laymen.

#### ELECTION OF OFFICERS.

The PRESIDENT asked for suggestions on the election of officers.

Mr. GOOCH said that they should ask the present officers to continue until the next Annual General Meeting (normally held in February).

Mr. RUDKIN said they were greatly obliged to their officers who had been serving, for what they had done for their country, and if they would continue to act for the Association they would be glad to have them. The suggestion was embodied in a resolution and carried.

The PRESIDENT thanked the meeting. He looked on it as a great honour that they should re-elect him. Those who had had the honour and pleasure of serving in the forces abroad had had anxious times, but when they came home on leave, they saw that those at home had difficulties and hardships to undergo. He had always done his best in the past to further the interests of the Association, it was always a pleasure to attend their meetings. He asked for the support of the members, and above all for better attendances in future.

The SECRETARY also thanked the meeting, though he had intended asking them to let him resign. He had been in office 16 years, and was getting older—(laughter)—at least older in business, and busier, but he would struggle on for another year.

#### A SCALE OF FEES.

The remaining item on the agenda was as to the arranging of a scale of fees for veterinary inspection and other duties, and the members gave some of their experiences with regard to the matter.

Mr. GOOCH said it was important that there should be unity. The Derbyshire Society had drawn up a scale of fees and were getting them. What was more, the system was killing the quack. The members of the profession simply refused to go to clients unless their scale-fees were paid.

The SECRETARY said he had neighbours who were quacks, and were accepted by insurance companies.

Mr. LOCKWOOD: Do they know whom they are dealing with?

Mr. GOOCH said one insurance society was doing business without any examination. At least they accepted a mare, and she was not examined until after she had foaled.

The mileage to be charged for visiting was also touched upon, and also fees for attending foaling, the amount charged in different parts of the district being found to vary considerably.

Mr. GOOCH said the only way would be to draw up a scale and discuss it, and get members to sign it.

Mr. RUDKIN: Why not adopt the Derby scale?

The PRESIDENT: He had not got the Derbyshire scale with him now, but he would suggest this should be brought forward at the next meeting. The whole question resolved itself into whether, since their society covered a very large district, it were possible to adopt a uniform scale of fees, circumstances altered cases considerably as he had said in his paper, but he thought they might adopt a minimum fee in nearly all cases.

Mr. GOOCH: I work for three different County Councils, and they are all different. He added that he had been working on the system of charging 25% above his pre-war scale.

Mr. TRUMAN said their fees were too low. He thought that they should take 50% above. Their Association covered a very large area, and circumstances were not all the same. In some parts people were more able to pay than in others, and a rigid scale was difficult to arrive at.

Mr. PORTER-SMITH said the scale would be the minimum; if they could get more, all the better.

The PRESIDENT said there must be some poorer people they could not make the same charges to.

Mr. TRUMAN said he did not want to put his name to a document unless he was going to keep it. In many instances poor people could not pay at all, and he

frequently attended cases where he knew he would never be paid so he never charged these people anything; whereas if he charged them half the minimum fee he would be up against the document.

It was resolved that a scale of fees, based on the Derbyshire scale, should be drawn up and submitted to the next meeting for discussion.

A vote of thanks to the President, on the motion of Mr. Truman, seconded by Mr. Rudkin, closed the business, and the meeting adjourned for tea.

#### ANNUAL ADMINISTRATION REPORT OF THE CIVIL VETERINARY DEPARTMENT, BOMBAY PRESIDENCY, FOR THE YEAR 1917-18. [abridged].

Lieut.-Colonel G. K. Walker held charge of the department throughout the year. He was on tour for 121 days and travelled 11404 miles by rail, 1003 by road and 40 miles by sea. He visited 13 districts, inspected 24 dispensaries and 6 stallion stands once, or more, and interviewed district officers and others in regard to the work of the department. He also investigated several outbreaks of contagious diseases.

Mr. J. D. Buxy held the post of the Deputy Superintendent and Personal Assistant to the Superintendent throughout the year. He was 108 days on tour and travelled 7255 miles by rail, 1787 miles by road and 150 miles by sea. He visited 16 districts and inspected 42 dispensaries and 12 stallion stands and attended several outbreaks of equine and bovine contagious diseases in the course of his tours.

During the year contagious disease was reported from all the districts and from the City of Bombay. In all 21137 deaths were recorded against 25801 last year. This is the first time for a number of years in which a decrease in mortality has to be noted. It is due to the fact that rinderpest and black-quarter were not so widely prevalent. The Gujarat districts were practically free from both these diseases throughout the year.

Since the Veterinary Assistants have been required to submit reports on the outbreaks attended by them as a routine it has been the custom to remind the revenue officials regarding the submission of statistical information where it had not been received. During the year 681 calls for such returns had to be issued from this office, which means that in practically all these outbreaks the figures would not have been received. This shows how a fully manned Veterinary staff would tend to accuracy in the statistics and until such time as this is provided they must remain more or less unreliable.

During the year the Veterinary Assistants attended 2025 outbreaks, of which 87 were also attended by the Veterinary Inspectors. This is fully a hundred more than the number of outbreaks reported by the revenue officials, showing that much is still to be desired in the manner in which the prevalence of disease is brought to light by the village officers.

Ninety-one cases of glanders were reported, all from the Bombay City. Surra was reported from eight districts and from Bombay City. There were 230 deaths as against 56 in the previous year. As equine diseases are very rarely reported by the revenue officials, these figures cannot be regarded as a complete indication of their prevalence.

Rinderpest was reported from 18 of the 20 districts. The total mortality was 13944 against 18502 last year. Although the disease was not so widespread as in the previous year it appears to have been of a more virulent character, the percentage of mortality being 53.22 against 48.9 the previous year.

Foot and mouth disease was reported in all districts except Dharwar. In all 349 deaths occurred against 284 last year. Mortality from this disease is generally

confined to young stock and is due to the neglect of the complications to which it renders them liable. Much benefit accrues to the public by the treatment of this disease by the Veterinary Assistants, and their services for this purpose are much sought after.

*Hæmorrhagic septicæmia* was widely prevalent affecting all the districts of the Presidency except the City of Bombay. 5323 deaths were reported against 2229 in the previous year. 523 outbreaks were attended by the Veterinary staff and the diagnosis of the disease was confirmed microscopically in 178 cases.

*Black quarter* was prevalent in 12 districts and caused 848 deaths. 106 outbreaks were attended and the diagnosis was confirmed microscopically in 36 instances.

*Anthrax* caused 158 deaths. Twenty-eight outbreaks were attended by the Veterinary Assistants and the diagnosis was confirmed by microscopical examination in 4 outbreaks.

Seventy-three cases of rabies came under observation during the year and the brains of 45 cases were sent for examination to the Bacteriological Laboratory, Parel.

#### PREVENTIVE MEASURES.

Inoculations against rinderpest amounted to 35380 in 288 outbreaks. 6190 uninoculated animals and 154 inoculated animals died in the course of these outbreaks. The decrease in inoculation is owing to the smaller number of outbreaks of rinderpest reported during the year.

In 122 outbreaks of hæmorrhagic septicæmia attended, 21027 inoculations were performed. 1414 uninoculated and 13 inoculated animals died in the course of the outbreaks where inoculation was performed. Inoculation against this disease has been introduced very recently but it has made good progress. There is evidence to show that where inoculation can be carried out at the beginning of an outbreak very satisfactory results are obtained, hence the rapid extension of this method of treatment in popular favour.

In 7 outbreaks of anthrax in the Kanara District 1,426 inoculations were carried out. Inoculations against anthrax are carried out only where the diagnosis of the disease has been confirmed microscopically. Forty-two uninoculated animals died during the course of the outbreak, whereas none of the inoculated animals died.

Vaccination against hæmorrhagic septicæmia was carried out in 34 villages where this disease is known to recur and 4784 animals were treated in this way, of which only one died. Vaccination against black-quarter was carried out at the Tegur Farm, Dharwar District, where 78 animals were vaccinated.

The number of villages visited by Veterinary Assistants during the year was 3132. They treated 29,611 cases of contagious disease and 15304 for non-contagious diseases during their tours.

1137 animals, mainly cattle, were castrated by the Veterinary Assistants on tour against 258 last year. This increase must be regarded as satisfactory in view of the strong prejudices that exist against castration, and it shows that the superiority of a surgical operation compared with the more inhumane methods of emasculation usually resorted to is being appreciated.

Maj. Liston, C.I.E., the Director of Bacteriological Laboratory at Parel, detected schistosomiasis in cattle, sheep and goats at the Bandra slaughter house and Veterinary Assistant K. B. Nair of this department was deputed to assist Dr. Soparkar in the investigation. It is probable that the disease is widely prevalent and inquiries are being instituted. The Superintendent is indebted to Major Liston and the members of his staff for their help in this matter.

*Veterinary Dispensaries.* There were 54 dispensaries in the Presidency during the year. The total number of cases treated was 161,211. The new method of recording these cases shows that 83461 animals were

actually treated at the hospitals, while medicines were supplied for 77750 cases to be treated at their homes. Last year the total number of cases treated was 161,668. There is no doubt that but for the prevalence of plague during the year, the number of cases treated would have been much greater instead of slightly less than last year.

No new dispensaries were opened during the year but arrangements were completed to open 7 in April of 1918. Sanction has been accorded to the construction of four dispensaries on the standard plan and there is also one already in hand. The funds for this work has been partly provided from the Wadia Trust.

More dispensaries are urgently required but owing to paucity of funds many District Local Boards are reluctant to undertake their share in their maintenance. This interferes with the progress of the department and a remedy is required if it is to approach anything like meeting public requirements in a reasonable time.

[There follows a satisfactory report of steady progress with Breeding operations, Cattle farms, Stallions, etc. Also a note on the establishment of Cattle shows, sanctioned by Revenue Department, eight of which were held during the year, and of which it is reported:—"It is too early to say what the results may be, but they certainly excited a considerable amount of local interest and keenness on the part of exhibitors. On the whole the commencement must be regarded as very satisfactory. The number of shows will gradually be increased in suitable cattle breeding areas according as experiment proves a success."]

*Subordinate Establishment.* The strength of the subordinate staff at the close of the year was—Veterinary Inspectors 5, Veterinary Assistants 84.

There were eight vacancies at the end of the year and five men were on military duty. The department were thus shorthanded by 13 men.

As in previous years four Inspectors were employed in charge of district work and one in charge of the Northcote Cattle Farm. The work of the Veterinary Inspectors is increasing, Veterinary Inspectors Marathe and Maniar did well in connection with the new schemes for premium bulls and village shows, Veterinary Inspector Nagarseth has as usual carried out the responsible work at the Northcote Cattle Farm, Chharodi, intelligently and efficiently. All the Veterinary Inspectors worked zealously and on the whole intelligently.

The members of the subordinate Veterinary staff have worked well. The reserves have been again very usefully employed in connection with outbreaks of contagious diseases.

The following Veterinary Assistants have done commendable work during the year:—D. B. Mamtara (Ahmedabad), M. A. Merchant (Surat), B. B. Patel (Bulsar), C. N. Desai (Broach), J. G. Kulkarni (Hubli), M. G. Kulkarni (Belgaum), A. B. Gadagkar (Dharwar), M. K. Garudachar (Sirs), F. Gracias (Poona Agriculture Veterinary Hospital), H. B. Shirsathe (Ahmednagar), M. B. Kulkarni (Reserve) and K. B. Nair (Reserve).

*General Remarks.* Lieut.-Colonel Walker states:—

"The work is developing in every direction and the need of more superior staff is becoming an urgent matter. Proposals have been submitted for an increase and for a simultaneous scheme for decentralization, the necessity of which has been previously pointed out.

"I wish to testify to my appreciation of the good work done by Mr. J. D. Buxy, the Deputy Superintendent, during the year. He has been of great assistance to me.

"The members of the clerical staff have also worked zealously."

G. TAYLOR,  
Officiating Superintendent, C.V.D.,  
Bombay Presidency.

[The usual tabular reports are annexed].

## A "CONTRACT" OFFER.

A correspondent sends us the following :—

"Dear Sir,—Enclosed please find a communication signed by Mr. John Hetherton the managing director of the County Insurance Co. and Stud Farm, and which is being sent to all persons in this district who insure animals in the company. Mr. Hetherton is the person who last year stated his company was prepared to finance veterinary surgeons at bank charges, provided they pushed business for the company, see the issue of the V.R., 18th May, 1918, p. 469. All the veterinary surgeons practising in and around York have worked for the company more especially for the Stud Farm."

The County Stud Farm, Sandburn,  
Stockton-on-the-Forest, York.

Dear Sir.—We have arranged with our veterinary surgeon, Mr. Bruce Selous, M.R.C.V.S., to provide attendance and medicine for stock belonging to those farmers who insure under our Whole Stock Scheme per prospectus herewith, for one shilling per head per month added to the premium.

This is a special advantage not given in any other district and we shall be glad if you will avail yourself of it. Our local agent will be glad to give you any information you desire and to take a Proposal for Insurance from you.

19th June, 1919.

Yours faithfully,  
JOHN HETHERTON.

## ARMY VETERINARY SERVICE

## THE ANNUAL DINNER.

The annual dinner of the Corps took place at the Savoy Hotel on Friday 20th June, the following officers were present :—

Major-General L. J. Blenkinsop, C.B., D.S.O., Director-General.

Major-Generals Sir R. Pringle, K.C.M.G., C.B., D.S.O.; Sir F. Smith, K.C.M.G., C.B.

Colonels : E. E. Martin, C.M.G., C.B.E.; W. D. Smith, C.M.G., D.S.O.; R. J. Stordy, C.B.E., D.S.O.; W. B. Walters, C.B.

Lieut.-Colonels : A. E. Clarke, R. C. Cochrane, G. Conder, D.S.O.; F. Fail, O.B.E.; H. Greenfield, C. B. M. Harris, D.S.O.; W. A. McDougall, D.S.O., O.B.E.; A. W. Mason, O.B.E.; J. W. Rainey, O.B.E.; J. Reilly, R. Rowe, W. E. Schofield, O.B.E.; W. J. Tatam, C.M.G., C.B.E.

Bt. Lieut.-Colonels : E. Brown, D.S.O.; A. Olver, C.B., C.M.G.; E. J. Wadley, C.B.E., D.S.O.

Majors : L. Daniels, P. W. Dayer-Smith, O.B.E.; T. G. Heatley, O.B.E.; F. T. G. Hobday, C.M.G.; T. H. Hobson, C. H. Hylton-Jolliffe, K. Mc L. McKenzie, D.S.O.; R. W. Mellard, D.S.O.; R. Porteous, P. J. Simpson, D.S.O., T.D.; W. Stothert, O.B.E.; F. W. H. Thomas, A. J. Williams, D.S.O.; Bt. Major W. Dennington, Quartermaster and Major T. E. Campey, M.B.E.

Captains : A. H. Andrew, J. Baxter, J. Bell, G. W. Bloxsome, H. Bone, M.C.; W. J. Cade, C. W. Cartwright, H. V. Fenn, J. Gregg, O.B.E.; J. J. Hilliard, O.B.E.; J. W. Hopkin, H. C. Jagger, O.B.E.; W. N. Jurgenson, R. D. Macintosh, C. S. Northcott, J. F. Player, C. Rees-Mogg, O.B.E.; A. W. Reid, T.D.; C. H. Sheather, R. T. Smith, A. Spreull, D.S.O., T.D.; G. Sutton, G. S. Thornewill, R. C. G. Thwaytes, A. E. Willett, Qrms. and Capt. C. Budd, M.B.E.; E. Epps, W. J. R. Gordon, J. F. Ives, R. H. Jameson, W. G. Thornton, Qrms. and Lieut. R. J. Easterbrook.

The following guests, Colonels A. E. Kendall, C.M.G. and C. E. Edgett, D.S.O., representing the Australian and Canadian Army Veterinary Corps, were present.

## Colloids.

The following is an extract from a Chadwick Public Lecture on "the use of colloids in health and disease," by A. B. Searle, given at the Medical Society of London on Wednesday, Feb 26th : Sir William J. Collins, K.C.V.O., M.D., Chairman of the Chadwick Trustees, in the chair.

"Very remarkable results have been obtained during the past few years from the study of a state of matter which is intermediate between that generally recognised as 'suspended' in a fluid and that in a true solution, and known as the colloidal state. Many substances of widely different composition and characteristics can be obtained in this state and their properties then differ in many ways from what would be anticipated.

The particles of colloidal matter are very minute, but by means of the ultra-microscope they may be recognised as endowed with violent motion. Many factors conducive to health depend on the possession of a colloidal character; thus the purification of sewage depends almost wholly on its ability to form a colloidal solution with grease and dirt. The researches of the late Henry Crookes, a son of Sir William Crookes—have proved the very effective germicidal power of elementary colloids; strikingly shown by a number of lantern slides of cultures of bacteria. This germicidal property soon led to their being employed as medicines as well as germicides—with remarkable results. Crookes' work has been followed by further investigations which have resulted in the preparation of silver, copper, mercury, manganese and palladium, and of such non-metallic elements as iodine and arsenic in the form of colloidal solutions which are isotonic with the fluids of the human body. These researches have made available a new series of liquids of great importance in the treatment of some of the most serious diseases. Amongst their most striking characteristics are their freedom from poisonous properties which render the same substances risky when administered in the form of ordinary solutions. Large doses of colloidal solutions may be given with impunity, and cures which are ordinarily prolonged, are effected rapidly.

Although the first remedial germicidal colloidal metals were first prepared in 1910, the rapidity with which they and other colloidal solutions have been adopted, and their extensive use in practice is a certain indicator of their value. Attempts to produce similar preparations were made by several German chemists, but most of the foreign preparations lack stability, and are decomposed before reaching the seat of the disease. The British colloidal solutions on the contrary are quite stable and effective.

The success which has attended investigations on the use of colloids as remedial agents is great and affords a basis of hope that further developments will be still more beneficial. It is probable that serum and vaccine thereby will ultimately be resolved into questions of colloidal chemistry, but in the meantime the use of colloidal solutions of certain elements appears to offer a means whereby they can be accurately prepared and administered with a higher degree of efficiency than is possible with some of the more complex synthetic compounds at present in use."

## Colloids in Medicine and in Industry.

A collection of admirable monographs on colloid chemistry and its general and industrial applications has been published for the Department of Scientific and Industrial Research by His Majesty's Stationery Office. This report, which is the second of a series, is the outcome of the work, during the year 1918, undertaken by a committee acting under the Chemical Section of the

British Association for the Advancement of Science. The first report was published in 1917, but the Association encountered financial difficulties consequent on the war, and found itself unable to meet the greatly enhanced cost of publication, and the question of publishing this second report of the work done in 1918 was referred to the Department of Scientific and Industrial Research. This department ultimately decided that the results of the work should be made accessible, on the grounds that they promised to be of considerable value to research workers in colloid chemistry and to many branches of chemical industry. It was therefore arranged that this second report should be published and issued at a price of 1s. 6d. net by H.M. Stationery Office on behalf of the Department of Scientific and Industrial Research. A wide field was covered, for the important subjects dealt with in the present report are as follows: Peptisation and precipitation, emulsions, the Liesegang phenomenon (formation of zones in jelly), electrical endosmosis (including electro-therapeutics, the electro-osmotic infiltration of drugs), colloid chemistry in the textile industries, colloids in agriculture, sewage purification, dairy chemistry, colloid chemistry in physiology, and the administration of colloids in disease. Our familiarity with the various properties of colloids shows considerable development since the time when Thomas Graham, in 1861, conceived the idea of the colloidal state of matter in his critical, though simple, experiments on the passage of fluids and gases through membranes and porous fabrics. Little importance at the time was attached to Graham's studies, and no one seemed to think it worth while to continue this line of research. Yet many years after it became obvious that the activities at work leading to the success of many great economic and industrial processes were based on colloidal conditions. Industry in its turn, as it has done before, opened up again suggestions of the highest value in medical researches, showing Graham to have been right in attaching importance to the part played by colloids in the principal life-processes. It was indeed a remarkable fore-sight which led him to write the following trenchant sentences in his communication to the Philosophical Transactions nearly 60 years ago: "The colloidal is, in fact, the dynamic state of matter, crystalloid being the static condition. The colloid possesses *energia*. It may be looked upon as the probable primary source of the force appearing in the phenomena of vitality. To the gradual manner in which colloidal changes take place may the characteristic protraction of chemical organic changes be referred." This is tantamount to saying that all life-processes take place in a colloid system, only those structures being considered as living which are at all times in a colloidal state: that is a view which receives acceptance to-day by the advanced students of bio-chemical research.—*The Lancet*.

#### Prosecution by R.O.V.S.

At the Police Court, Ware, on Tuesday morning, June 3rd, before Messrs. J. H. Buxton (in the chair), S. Croft, A. H. Rogers, C. N. Tween, and H. S. Gilbert.

Samuel Smith, Melton, Yorkshire, did not appear to answer a summons for unlawfully using and taking the title veterinary surgeon, not being duly registered as such, on March 19th.

Mr. H. M. Gisby appeared for the Royal College of Veterinary Surgeons, and stated that he received a telegram that morning from defendant addressed to his employers saying that he had missed the train, and asking them to do their best. The prosecution was under section 17 of the Veterinary Surgeons' Act, 1881. The

College naturally had to protect their duly qualified members, and it was of the greatest public importance that they should do so. They had to ask that such cases be dealt with severely. The evidence in the present case was that defendant examined a horse which was to be sent to Ireland. The Board of Agriculture required that for every animal so transported there should be a certificate signed by a duly qualified veterinary surgeon stating that the horse was free from disease. Defendant signed such a certificate, but the official in Ireland to whom it was sent, on looking up the register of veterinary surgeons, found that his name was not there, and reported the case for prosecution.

George Howard Gibbons, 33 Essex Street, Strand, London, clerk to the solicitors for the Royal of Veterinary Surgeons, proved that defendant was not duly qualified.

George Nicholson, Round House, near Ware, stud groom to Col. R. P. Croft, gave evidence of witnessing defendant sign the certificate (produced).

Mr. Gisby said he submitted that the case was duly proved, and asked for a conviction with costs of the prosecution.

The Bench retired to consider their decision, and on returning the chairman announced they were of opinion that the charge was proved, but they were also of opinion that the defendant committed only a technical offence. They would not record a conviction, and they considered the case would be met on payment by defendant of £2 2s. towards the costs of the prosecution. The court costs would be remitted.—*The Hertfordshire Mercury*.

#### Failing to notify mange.

The following is reprinted as it appeared in *The Surrey Times* of June 21st.

#### Veterinary Surgeon Fined.

Before the Guildford Borough magistrates on Monday, Harry James Boylett, 16 Trinity Churchyard, Guildford, was summoned for that he being a veterinary practitioner employed to examine a horse at Guildford, did fail to notify with all practicable speed the suspected existence of parasitic mange therein to an inspector of the local authority during the month of April.—Mr. W. Price Hughes appeared for the defence.

George Hedges, Down Road, Merrow, managing Watford Farm, said he let a horse out on hire some time ago, and it returned to the farm in April. The horse developed a sore, and he called in Mr. Boylett. He said he thought it was the mange, and that he could report it if he liked. He said he would give him a bottle of disinfectant, which witness called for.

Albert Butcher, Watford Farm, said he knew Boylett very well. He had treated his animals on several occasions.

John A. Cunningham, M.R.C.V.S., said on May 5th he was called in by the Borough Police, and found the horse had parasitic mange of some standing.

The Chief Constable (Mr. W. V. Nicholas) said no notice was received that the horse was suffering from parasitic mange.

Mr. Price Hughes said defendant had no diplomas, and did not pretend to be a veterinary surgeon. If the bench upheld that he was a veterinary practitioner, he would plead guilty to a technical offence.

In imposing a fine of £5, the Mayor said the magistrates considered that it was a very serious case.

## Personal.

Mr. J. F. Durkie, J.P., M.R.C.V.S., who is a practical farmer and member of the Dundee Harbour Trust, has been appointed by the latter to represent them on the deputation which is to meet the Board of Agriculture in London to discuss the question of raising the embargo on the import of Canadian cattle.

## Veterinary Societies—Addresses.

## BORDER COUNTIES V.M.S.

Pres: Mr. H. Barrow, M.R.C.V.S., Ireby, Carlisle  
Hon. Sec: Mr. R. Craig Robinson, M.R.C.V.S., Carlisle  
Meetings, Second Friday of Feb., June, and October

## DERBYSHIRE V.A.

Pres: Mr. A. Levie, F.R.C.V.S., Derby.  
Sec: Mr. F. T. Prince, M.R.C.V.S., Ashbourne.

## DUMFRIES AND GALLOWAY V.M.A.

Pres: Mr. T. M. M'Connell, Wigtown.  
Hon. Sec: Mr. N. H. McAlister, Kirkcudbright.

## GLASGOW V.M.S.

Hon. Sec. Mr. John S. Keane, 11 Falkland Mansions,  
Kelvinside

## ROYAL VETERINARY COLLEGE V.M.A.

Pres. Capt. J. T. Edwards, B.Sc., M.R.C.V.S.  
Treas: E. S. Shave, Esq., F.R.C.V.S., M.R.C.S.  
Sec: Mr. B. Gorton, M.R.C.V.S. Asst. Sec. C. W. Heane.

## NATIONAL ASSOCIATION OF VETERINARY INSPECTORS

Pres: Major J. Abson, F.R.C.V.S., Sheffield  
Hon. Sec: Mr. Trevor Spencer, M.R.C.V.S., Kettering

## ASSOCIATION OF VETERINARY OFFICERS OF HEALTH

Pres: Mr. T. Douglas, M.R.C.V.S., Kilmarnock  
Hon. Sec: & Treas. Mr. A. M. Trotter, M.R.C.V.S.,  
Moore Street, Abattoir, Glasgow

## MUNSTER VETERINARY INSPECTORS' ASSOCIATION

Pres: Mr. D. M. Barry, M.R.C.V.S., Mallow  
Hon. Sec: Mr. J. F. Mahony, M.R.C.V.S., Caroline St., Cork

## NATIONAL VETERINARY BENEVOLENT &amp; MUTUAL DEFENCE SOCIETY.

Pres: Mr. W. A. Taylor, F.R.C.V.S., Brick-st, Manchester  
Hon. Sec: & Treas: Mr. G. H. Locke, M.R.C.V.S.,  
Grosvenor Street, Oxford-st., Manchester

## VICTORIA VETERINARY BENEVOLENT FUND.

Pres. Mr. S. H. Slocock, F.R.C.V.S., Montague Rd, Hounslow  
Hon. Secs. Mr. P. J. Kelland, M.R.C.V.S.,  
Mr. Fred Bullock, F.C.I.S.,  
10 Red Lion Square, London, W.C. 1.

Will Secretaries please intimate alterations.

*Meetings*, Second Wednesday, May, Oct. and January

Five columns started from the neighbourhood of Pretoria and were to advance due east, where they would be joined by three more advancing successively from the north, the whole converging and moving south-west would, it was hoped, eventually bring the forces face to face with the enemy in the bottom pocket of the Transvaal.

On 28th January the first five columns began the advance, driving east on a line 30 miles in length. The marches were about 15 miles a day, and were intentionally short, as a good deal of work had to be done on the road. It is a long story, but in brief all the commandos belonging to the places traversed passed through the meshes of the net. The only forces remaining before the driving line being those drawn from the extreme S.E. of the Transvaal, towards which the "drive" was taking place. These pushed along covering the retreat of their families and stock, now turned out on the veldt.

Very skilful management was required to secure the due co-operation of all the columns and their regular feeding. Smith-Dorrien, in command of one of the two columns passing from north to south was escorting an immense supply of food and stores. Before he could link up with the five columns going east he was attacked at night by Botha near *Lake Chrissie*. The horses and transport were parked in the centre of the camp, and hedged in by infantry battalions. At 3 a.m. on a pitch dark night a crushing magazine fire was suddenly opened on the sleeping square, which stampeded the horses of the 5th Lancers and Imperial Light Horse, thereby intensifying the confusion which naturally existed. These horses broke out through the square, and galloping towards the enemy were turned and driven back. In the confusion thus caused the enemy destroyed two of the pickets, but no further damage was done, and Botha shortly afterwards withdrew and escaped from the net. This attack cost Smith-Dorrien 300 horses killed or stampeded.

Steadily all the columns continued to converge on the S.E. corner of the Transvaal, and were now lined up from Swaziland to Natal, thus cutting off the S.E. pocket which ends at Zululand. Rear-guard affairs were frequent, and the columns struggled to get into position. The critical moment had now arrived, but the operations were delayed by weather and want of food. Supplies were coming from Natal, but the weather was dreadful, the roads impassable, the country most difficult for wheeled transport even under favourable conditions. The first part of the convoy, consisting of 160 waggons, left Newcastle on February 12th and reached Utrecht on 13th. The road from Utrecht to Luneberg is only 35 miles, but steep and there are at least three rivers to cross. It took two days to get the convoy nine miles up a long and steep ascent, and on 17th the rain fell. For six days and nights it rained without ceasing; every spruit became a raging torrent, and roads were axle-deep in mud, the waggons were bogged,

and the troops lying in the open over a front of 80 miles were starving for the supplies so near and yet so far. Finally, supplies had to be sent across the river by wire rope, and this expedient, together with pontoons and rafts, had to be used on two or three other rivers, so as to lighten the waggons considerably for the wretched oxen to get them across. It was the 2nd March before supplies reached French; on the 7th the men were temporarily on full rations, but the horses got merely a microscopic allowance of corn and the mules nothing whatever for a fortnight later.

For two weeks the men had had no food but what could be obtained locally with great difficulty. On 6th March the rain again began, and it rained continuously for eight days. From the 16th Feb. to the 16th March the troops were immovable under the terrible climatic conditions mentioned, and in a state of semi-starvation. If this was the case with the men, that of the animals was worse. The deluge and the break down in the transport of the supplies doomed this sweep to failure. When the weather cleared it was again pushed on, but with very little success; the Commandos melted away. Botha was outside the ring fence, in fact was riding into the Free State to talk over with De Wet the results of his raid into the Colony, and was back again at Bethel while our troops were hemmed in by floods and tied down by starvation with their heads facing the other way.

The results of these operations were disappointing. They involved the loss of two and-a-half months in time, and from a military point of view may be regarded as practically barren. A large amount of stock was captured, according to the Official History\* 272,000 head. The "Times History" places it at "between 7000 and 8000 horses and mules, and a quantity of cattle which it would be profitless to reckon, since through sheer inability to keep or kill them the greater part escaped."†

Immense supplies were captured or destroyed, yet we have seen our force starved, showing the difficulty of carrying food on its feet, and the waste of food supplies which occurs in this class of warfare. The flour which is burned to-day because it cannot be carried may be worth its weight in gold in a day or two.

The loss of horses in this drive was estimated at 2000,‡ but this can only refer to the dead loss. Casualty returns for one column (that of C. E. Knox) show that between 27th Jan. and 12th April the total loss of horses was 50%, and the dead loss 20%. Only seven horses in this column were killed in action, 255 were destroyed, 64 died (all from horse sickness), and 36 were missing or abandoned.

Assuming the above figures to apply to the other columns, the estimated total loss may be taken at 5000, and the dead loss at 2300. The latter figures

\* Vol. IV., p. 122.

† Vol. V., p. 181.

‡ Cd. 963, p. 49, Cable 79.

then compare very well with the above official cable, which was despatched on 20th March before the operations were concluded, for on 26th March the columns were occupying a line 120 miles long, and from this further operations occurred which were not concluded until 13th April.

A return for Alderson's Column between 8th January and 22nd April gives the astonishing total loss of 80% (nearly), due to exhaustion, debility, sore backs, and horse sickness. The dead loss is unknown.

The losses from "horse-sickness" during this "drive" were very heavy, as the columns were operating at the worst season of the year. Starvation also played an important part, as may be seen from the following table of the daily amount of corn issued per horse:—

Jan. 26 to Feb. 10	10 lb. corn daily		
Feb. 11 " 20	8 lb. "		
" 21 " "	3 lb. "		
" 22 " 28	nil		
Mar. 1 Mar. 12	8 lb. "	mules nil	
" 13 " 20	nil		
" 21 " 25	10 lb. "	" 5 lb.	
" 26 " 30	7 lb. "	" 3 lb.	
" 31 onward	10 lb. "	" 5 lb.	

The cause of this starvation was the breaking down of the transport referred to above, owing to the days and nights of continuous rain. The loss would have been far greater but for the fact that grazing was possible at a time when military operations were impossible. The continuous wet, together perhaps with the irritating effect of dirt caused a large number of shackle and other wounds to assume a very unhealthy condition, resembling in appearance and indolence the "veldt sores" which affected the men.

During this long drive across the Eastern Transvaal fresh measures had been adopted for the care of sick and debilitated horses; each column was directed to maintain a small permanent staff under the veterinary officer for this purpose. The animals were brought on quietly with the convoy in rear, grazing as they travelled, and the relatively short marches enabled this rough and ready system of mobile hospital to be rendered most useful. The cases were dressed on reaching camp. No transport was allowed for these hospitals. Even at this period of the war the essential factor for field hospital organisation was denied. The whole question of hospitals will, however, be considered in a separate section at the end of 1901.

#### ORANGE FREE STATE.

OPERATIONS FEBRUARY-JUNE, 1901.

#### ELLIOTT'S "DRIVES."

The only column returning to the Free State in the chase after De Wet, the movements of which we have noticed, was that of Plumer (p. 156). The others followed, some crossing at Norvals Pont, others to the west at Orange River Bridge on the Kimberley line. Thus twelve columns came bust-

ling back into the Free State. C. Knox, Crewe, Pilcher, and Bethune crossed at the Orange River Bridge and scoured the country in the direction of Bloemfontein. This was entered a fortnight later after meeting with constant opposition from small bands of the enemy, which, though not identified at the time, were the commando fragments shed by De Wet's main body as it proceeded north. Among those crossing in the east at Norvals Pont were Haig, who made for Hertzog in the direction of Luckhoff, but was then called to the line, arriving at Edenburg on 10th March. Hickman and Thornewcroft also crossed, and were at Springfontein on 9th March. Under the command of General Lyttleton a big "drive" up the eastern part of the Free State from the Orange River to the defended line running between Bloemfontein and Basutoland was now organised with the three eastern columns above mentioned, together with the three under Bruce Hamilton. On the 10th March it began to advance, hampered by tired animals and mud, and as it slowly rolled northwards Bethune and Pilcher were able to take part in the sweep which, excepting for stock, was nearly destitute of military results. It terminated on 20th March, 4300 horses were captured and enormous masses of stock. Bearing in mind the cockpit this area of the Free State had been for a whole year of the war, and the scores of columns belonging to both sides which had traversed it, it is astonishing to find so many horses among the captures, and indicates the extraordinary resources of the country which we were now only attempting to utilise. So great had been the drain on the Remount Department that it was found impossible to meet the ever growing demand except by utilising the animals of the country after the enemy had selected the best.

Another sweep was made by the three columns of Bruce Hamilton, together with that of Hickman, from the Basuto border towards Dewetsdorp and Wepener, and from there concentrated south, as Kritzinger, who was still roving about Cape Colony, was expected to cross the Orange and endeavour to get north. Sweeping columns were also working in the vicinity of Heilbron under E. C. I. Williams. Rundle's two mobile columns of Campbell and Harley, to which Pilcher was later joined, were sweeping around Ficksberg, Thabanchu and Vrede, while Paris, who had returned to Kimberly on 12th March, after the De Wet hunt, swept up to Boshof and returned with large quantities (9000 head) of stock.

It was now April, 1901, and the change from seasoned to unseasoned soldiers had been going on for many weeks. The importance of this change from a horse-wastage point of view is considerable, and in considering animal losses during 1901 it must not be lost sight of. The M.I. which we first saw at Rameh in February, 1900, had long been a fine body of soldiers, the back-bone of many a column, but the toll of a thirteen months campaign is heavy, and drafts from these regiments amount-

ing to 2000 men had now arrived in the country with very limited experience. Some of these received their first insight into war by assisting in the chase after De Wet (p. 154), but all needed time for development.

In March Major-General E. L. Elliot arrived from India for the purpose of assuming Command of a Division 6000 strong, composed of the columns of Broadwood, De Lisle, and Bethune\*, which was concentrating at Kroonstad. Owing to the fact that his ranks were filled with inexperienced soldiers, and his horses either remounts or just off board-ship, Elliot wisely determined to make his first drive educational. He selected the west of the line between Kroonstad and the Vaal, and on 10th April marched north towards the latter in easy stages, and turning east converged at Vredefort Road on 20th. The opposition had been slight, but De Wet, who was on his way south to Petrusberg, could not resist the temptation of capturing a patrol. In this sweep Elliot obtained 35,000 head of stock, 184,000 lbs. of grain, and many waggons. E. C. I. Williams, who was independently working the Vaal between Heilbron and Frankfort, brought in 14,500 head of stock, and had destroyed tons of flour and the mills which had ground it. † This destruction of food stuff appears strange in the face of the feeding difficulties the troops experienced, but the material could not be transported.

Elliot's second "drive" was now projected, the principal of which was that his three columns should move on a broad front of 40 miles, the flanks of which would touch Heilbron and Lindley. Into this driving line as it advanced the enemy was to be forced by other columns operating from the north and south. A wheel to his left would then bring his columns facing the Vaal on which he was to advance, and into his arms the scattered bands were to be driven by columns operating from the Transvaal (Heidelberg and Standerton). This was not all, having reached the Vaal the force was to move south-east and sweep the country bordering on the Klip River as far as the north point of Natal.

The operations began on April 24th, and by the 28th Reitz had been touched in the wheel north from Lindley. On 30th Frankfort was reached, and on 4th May the Vaal. On 7th the force moved south-east to Vrede, and at De Lange's Drift over the Klip River contact was made with Colville from Standerton to whom the spoils of the drive were handed, amounting among other things to 70,000 head of stock and many waggons, 9000 head of stock had previously been sent back to the line *via* Heilbron. A four days sweep along the Klip brought the force on 19th May to Botha's Pass in

northern Natal, where 2200 captured horses, 600 oxen, and 16,000 sheep were despatched to New-castle. Twenty-five miles west of Botha's Pass Elliot discovered a place not figured on the maps, an isolated horseshoe-shaped series of hills ten miles in length and of fantastic shape, "crags so sheer, and so squarely hewn by nature, that the hills appeared to be crenelated by a parapet of Norman castles." This place was a magazine and remount depot for the Free State forces. It was raided by Elliot, who captured 1700 horses which he sent into Harrismith by De Lisle.

Elliot on 3rd June was directed to return to Kroonstad *via* Reitz and Lindley; on 6th June a laager of the enemy was raided, and a large convoy captured by a small party of the 6th M.I. and South Australians belonging to De Lisle. This force in turn was set upon by a superior body of the enemy, which compelled the party to seek shelter in a kraal and leave the captured waggons. Fighting was carried on by picked shots at 50 yards range and resulted in heavy loss on both sides. The horses were partly covered by the walls of the enclosure, nevertheless 100 were killed and 50 wounded. †

Elliot's Division reached Kroonstad in June after a march of not less 800 miles, and the following were the casualties during the seven weeks covered by the operations:—

Died and destroyed	-	567
Killed in action	-	177
Stampeded or captured by enemy	-	51
Sent to hospital during the march	-	216
Sick on arrival at Kroonstad	-	1430 of which
631 were surgical cases, principally lameness.		

Taking the strength of the Division on leaving Kroonstad to be 6000, the total wastage amounts to 40 per cent., the dead loss to 13½ per cent.

The total number of mules employed with the Division was 2252, of which only 36 died or were destroyed. Of 1600 oxen only 36 died. These figures for the transport are very good, and due to the short marches made and the care taken that the animals were invariably outspanned, watered and rested at mid-day.

The food allowance for horses was 10 lb. grain and 6 lb. for mules, in both cases a mixture of maize and oats. The enemy started veldt fires around the column, always so arranging that the fire was driven towards it. Under the cover of this attacks were frequent, but the most serious result was the loss of grazing to the animals; fortunately the worst trouble in this respect was towards the end of the march.

\* "Official History," Vol. iv., p. 104

† Curiously enough, both De la Rey and De Wet were in this attack, the former had come on an official visit to meet President Steyn. The redoubtable trio were disturbed at breakfast by a messenger, who informed them of the captured convoy and laager. Accordingly they went to its rescue, and but for the appearance of De Lisle, four hours after the fight began, there is no doubt what the result would have been.

\* The following Veterinary Officers were with General Elliott:—Major Mann, S.V.O., Capt. Boase, Cape Colony Forces, Lieut. Lockwood, I.Y., Lieut. Anderson, I.Y., C.V.S. Parker, Crawford and Farrell.

† "Official History," Vol. iv., p. 101.

The total amount of stock collected by this Division was immense, amounting to 131,500 head; of these 15,000 were horses. One thousand of the captured horses were utilised during the march to replace casualties, but they were very unfit, and after being ridden four or five days were returned to the "mob" which was being driven along with the columns. On an average 20% of the captured horses were suitable for the ranks after training, and 40% were such as might be utilised by the enemy for a few days. The remainder were foals, yearlings, or mares too heavy in foal to be able to gallop. These figures are of interest in considering the proportion of horses in Cape Colony which might have been utilised as remounts. The estimate was made by Major Mann, A.V.D., S.V.O., of General Elliot's Division after weeks of observation.

The chief sickness met with during the march was biliary fever: the most usual cause of death was exhaustion. The surgical cases were principally lameness, sore backs and heel galls. No less than 111 cases of sore back and heel gall were sent to Standerton by Colville from the 1st and 3rd Dragoon Guards and Broadwood's Yeomanry. The chief cause of lameness was laminitis; the horses could not be kept shod, in fact, there was not a shoeing smith in the whole of De Lisle's M.I.

The Division had a veterinary hospital, which was fixed at some convenient point, generally Heilbron, for the reception of cases. It moved between Heilbron and Kroonstad, but it was found that it would have been of more use had it accompanied the Division.

Other operations occurring in the Free State may now be noticed. Rundle's two mobile columns had for some time past been holding positions as garrison troops; one of these, Campbell's, was finally available for raids, and on 20th April Rundle with this column moved out of Harrismith for Bethlehem (50 miles). It is characteristic of the state of the country at this time that, to reach Bethlehem, cost him four days incessant skirmishing.† On 29th, Rundle entered the Brandwater basin, reaching Fouriesburg on 2nd May, where for a month he operated from this point. He left the basin on 4th June with 6000 head of stock. His 500 new Yeomanry, "some of whom had scarcely learned to ride, were found impotent in the wild ravines of the Wittebergen."‡

Between 22nd April and 8th May Pilcher and Thorneycroft raided the Winburg, Senekal and Doornberg area. From the 13th to 22nd May both of these columns worked in the direction of Bothaville, Commando Drift and the Vaal, having numerous encounters, and returning to the line with 5000 head of stock.

The six columns guarding the Orange River under Lyttelton in March had little to do, though

there were several sharp encounters with local bands, including a 40-mile march by Munro with a large haul of prisoners. The Trans-Caledon region was now ordered to be cleared; this was the recruiting ground of Kritzingen, who, in spite of the numerous columns along the river was actually, though unknown to his enemy, obtaining horses in the Free State in May. He experienced no more difficulty in returning to Cape Colony than he had in leaving it. The first sweep of the Caledon district produced 97,000 head of stock. The general trend of the columns was now in the direction of Cape Colony; Munro, Haig, White and Hickman had all gone thither before the end of May. In the same month W. H. Williams had swept along the north bank of the Orange River to Orange River Station, and was surprised to find the country still full of stock. He returned with nearly 100,000 cattle and sheep.

Bruce Hamilton's information lead him to organize a sweeping movement from south to north of this part of the Free State between the Orange and Modder Rivers. Seven columns were made out of his original three, and with the co-operation of C. Knox a drive was organised against a barrier of posts held by the Constabulary, and thrown out across the Free State. But though it employed eleven columns it lead to no important results. The whole of the Free State between the Vaal and Orange Rivers, and west of Bloemfontein was now for the remainder of the month continuously raided by six columns. Simultaneously to the east of the railway, *i.e.*, in the Reddersburg-Dewetsdorp area, three columns ravaged the country, and though large quantities of stock resulted from these raids no conclusive military results were obtained.

On 22nd June, Elliot started off from Kroonstad on another drive, this time with four mounted Brigades, Bethune's, De Lisle's, Broadwood's and Lowe's, a total of 5670 horses, 2826 mules, and 1840 oxen. He swept the country between Lindley and Senekal, the objective being Springfield Drift near Harrismith. This was reached on 2nd July, and was effected by forced night marches and night raids, but all were fruitless for the enemy had full warning, moreover, they were most exhausting to animals; Elliot captured 3000 horses and 3000 cattle. This march to Springfield was more exhausting than those previously carried out, for water was scarce and the veldt burned. From Springfield the Division, in co-operation with Rundle's three columns, swept north over a frontage of 50 miles, taking in Reitz. At this place Broadwood contrived a surprise for a Commando, but found he had captured all the Free State Government with the exception of President Steyn, who escaped under remarkable circumstances.\* Elliot returned to Vredefort Road *via* Heilbron, which he reached on 13th July.

\* Six thousand sheep were destroyed for footsoreness, or for inability to cross the drifts.

† "Official History," Vol. iv., p. 15.

‡ "Times History," Vol. v., p. 241.

\* The President was only 80 yards away from a man who was an expert shot, but whose rifle refused to work through the oil being frozen in the breach! The horses had already done 30 miles, so he could not be galloped down.

The casualties from the 22nd June to 13th July were 4% dead loss and 10% total loss.

It was during the March from Springfield to Heilbron that the new order was carried out of destroying all captured animals not of use to the force. Such work cannot be satisfactorily done while troops are marching daily, for time does not admit of the needful careful draughting, it therefore becomes very wasteful. Elliot brought back 4000 horses, 3,600 cattle, and 54,000 sheep.

Rundle, leaving Elliot, continued his movement to the north, sweeping up immense supplies and stock, 10,000 horses, 6,000 cattle, and 46,000 sheep. We have seen that Elliot had only a few weeks previously passed over part of this ground, yet Rundle's movement resulted in the above captures. Column after column had yet to move about and through this country before it could be declared swept. Having reached the Vaal south of Stander-ton Rundle returned to Harrismith, arriving on 3rd August.

Rimington now entered the Orange Free State from the South-Eastern Transvaal, where he had been employed together with Plumer in the Wakkerstroom clearance. He, like Benson, had adopted the method of night-raiding and day-resting. By this means he rested and fed his horses, and the result was to render him the most mobile and dangerous adversary which the enemy in the Free State could meet. From the middle of July to the end of August he was in the Heilbron-Kroonstad area, constantly engaged in clearing—that is to say destroying or removing supplies, stock, agricultural produce, and implements—and fighting. He imitated the "doubling back" methods adopted by the enemy; he travelled immense distances, 60 miles in a night, and rarely without some profitable results.

All this was due to his skill as a horse-master, of which he probably had few equals and no superior in the field. None knew better than he the value of food, rest and condition, and the necessity for the constant supervision of the master's eye. The veterinary officer with him was C.V.S. (now Capt. Head, A.V.C. Reserve, and we are fortunate in having from the pen of that officer\* an account of the changes which were brought about in the horses of the Inniskilling Dragoons when Rimington assumed command in January, 1901. Under this commander the neglect of horses became a crime, and men who through carelessness laid their horses up marched on foot, and on arriving in camp were placed on picket duty. His great object was to interest them in the care of their horses, and to be proud of their animal's fitness and condition.

All this required time to effect, but with Rimington progress was steady. We now meet him in the following August an efficient fighting machine, with horses capable of real hard work, to gain

which all non-essentials were sacrificed. Neither comfort nor appearances were studied, and not an ounce of unnecessary weight was carried on the saddle. He did not destroy supplies if he could carry or eat them; he never passed a water supply without watering his horses; nothing excepting military pressure would induce him to pass a place where grazing could be had. His horses came first in everything; his men, as he himself said, were capable of looking after themselves.\* Rimington did not learn horse-mastership in the Field; like Benson and De Lisle he brought the knowledge with him. It was untingered by the Epsom salts, diuretic ball and tonic powder management so common in the Artillery, where fatness and fitness are frequently confused.† He knew what horses could yield under generous care and treatment, and he stands out not as a solitary, but as one of the highest examples of horse-mastership in the war.

\* R.C. Erid., Vol. ii., Q. 12,672.

The evidence of this officer before the Royal Commission, Vol. ii., p. 26, is a liberal education.

Q. 12,663. And you think the question of horse management is one of the first things in a campaign?—A. Absolutely the first thing—it is 75 per cent. of the campaign as far as I can see.

Q. 12,664. I see you used rather drastic measures with the men who did not treat their horses well?—A. Yes, we made their lives a burden to them.

Q. 12,668. You do not mean that there should be any disregard of the health of the men?—A. I disregard the men's health completely compared with the horses. A man can speak up for himself, and will no doubt do so and go to the doctor, but the horse cannot say anything.

Q. 12,671. I do not quite understand what is meant by this statement which appears in your précis "With all mounted troops extreme severity and absolute disregard for the men's health, feelings, or safety is necessary in this respect?"—A. Yes, the horse is the first thing absolutely. You must look after that . . . . .

Q. 12,672. . . . . —A. I look after the horse first—the man looks after himself.

Q. 12,673. But the horse would not be of use without the man?—A. We found that there were plenty of men; we never were short of men, we always were short of horses.

Q. 12,674. Still the life of a man has to be thought of?—A. What is the life of a man? A man's life is nothing in war. You do not care whether men are killed or not as long as you attain your object.

Q. 12,676. . . . . —A. I put the horse first. As long as I have plenty of horses I can manage. I do not mind about the men.

† Reference has been made at p. 117 to the organization of the Artillery. As horsemasters they have no superiors, devotion to the welfare of their animals is part of their service creed. Unfortunately they love drugs and nostrums, and attribute to these, results which are really the outcome of their own admirable care and supervision. Their weak spot is their love of a fat horse.

## TRANSSVAAL.

## WESTERN TRANSSVAAL,

FEBRUARY-MAY, 1901.

The events immediately prior to those now to be recorded have been noted at p. 156. It was all important to keep the Western Transvaal quiet while French's big drive in the Eastern portion was taking place. There was no great activity on the part of De la Rey for the reason that he was short of horses, and had eventually to purchase in the Free State.\* He was now to the west of the Magaliesberg in an impossible country for British columns. Babington was lying in an entrenched camp a few miles south of Olifant's Nek, and a force was at Roodepoort near Krugersdorp which had recently been repulsed by Smuts in the Gatsrand. Two new columns were formed to dislodge the latter, Shekleton with 1200 men of the M.I. just arrived in the country, and Benson with a very mixed column of odds and ends, comprising 580 mounted men, infantry and guns. Smuts escaped after the columns had been marching for a week, and in the early days of March Kemp also disappeared to join De la Rey in the west, stealing past Babington in the night. Meanwhile, Methuen in the far west at Taungs was moving east on Klerksdorp, and was intercepted by De la Rey at *Hartebeestfontein*, close to Klerksdorp, and had to fight his way in. His march was 150 miles. He then turned south to cross the Vaal into the Free State for the relief of the garrison of Hoopstad, but was unable to cross the river owing to floods, and had to work along the bank to Fourteen Streams, which he reached on 14th March. After relieving Hoopstad he spent all April getting his force in order, for he had now lost all his old Colonial troops; his Yeomanry also were leaving and being replaced by the second contingent.

During Methuen's journey along the Vaal to Fourteen Streams, *Lichtenburg* was attacked and invested by De la Rey on 6th March; it made a gallant defence. Among the garrison were 100 Yeomanry. Their horses were saved from destruction during the investment by being placed in the Dutch Church. Babington and Shekleton were sent to the assistance of Lichtenburg, and leaving Ventersdorp on 15th March took the wrong direction; while they were going west the enemy opened out, allowed them to pass by and then went south. Fortunately the error was discovered. The columns were attacked by De la Rey at *Geduld* on 22nd March, where the enemy again put into practice their new manœuvring of charging and firing from the saddle. The two columns closed in, and De la Rey retreated hampered by his transport. He was pursued, and again the next day until the horses could go no further, but the results, especially at *Wildfontein* on 24th March, in captures were excellent, and both columns returned to Ventersdorp. A shuffling of Column Commanders now occurred in April; Shekleton being replaced by

Rawlinson, and Benson passing to the Eastern Transvaal for the Northern operations. De la Rey dispersed his forces. Babington and Rawlinson, after a good deal of marching in wet weather, surprised Smut's laager on 14th April at *Braakpan*, 25 miles north-west of Klerksdorp, and again made good captures. In spite of these successes the enemy hung about in the triangle formed by Ventersdorp, Lichtenburg and Klerksdorp. Meanwhile Methuen was railed to Mafeking and marched to Lichtenburg, where he arrived on 3rd May; five columns operating from the east worked towards him, but everything appears to have gone wrong, and the operation was nearly barren of results.

## STRENGTH OF COLUMNS.

Lieut.-Col. Benson	-	-	360 horses
" Sir H. Rawlinson (late Shekleton)	-	-	1500 "
Brig.-Gen. Dixon (late Cunningham)	-	-	1050 "
Major-Gen. Babington	-	-	860 "
Lieut.-Gen. Lord Methuen	-	-	1290 "

With the exception of the force under Methuen and the chase on 23rd and 24th March there were no long marches performed by these horses, but the work, though interrupted for two or three weeks at a time, was very trying, especially as the change from old to new Colonials and Yeomanry Contingents was occurring. Dixon, for example, received several hundreds of men during April, and had, like Methuen, to devote that month to their training.

During the operations narrated horse sickness was very prevalent among the columns, the district in which they were moving being notoriously infective. Mr. F. B. Gresham, of Newark, who was C.V.S., with Shekleton's, and afterwards, Rawlinson's columns, tells me that during March Shekleton's column lost 32 animals from this disease. He has also been good enough to give me the general return of sick for that month, which is here produced as evidence of this class of wear and tear.

## SHEKLETON'S COLUMN.

Strength in horses	1499	} Remounts received during	
" mules	470		the month 534
Deaths	-	-	60
Destruction	-	-	100
Abandoned	-	-	4
Loss by captures	-	-	15
			179

The monthly dead loss was 9%, of which only a trifle (four animals) occurred in action. In addition there was at the end of the month a sick list of about 140 animals, made up principally of sore backs (87 cases), lameness from contusions (25 cases), and exhaustion (28 cases).

Mr. Gresham has been able to furnish me with three months' wear and tear in the 2nd Regiment of M.I. which belonged to this column.

	Original strength	Died and destroyed	Missing
Feb. 1 to Mar. 8	355 horses	32	5
Mar. 9 May 3	465 "	75	1
May 4 May 31	489 "	49	1

\* "Times History," Vol. v., p. 218.

In three months this regiment suffered a dead loss of 160 horses, or nearly 11½% a month, this is quite exclusive of the temporary loss due to sickness. Horse sickness and inexperience of horse management were responsible for nearly all these losses.

We are now in the middle of May. Everything pointed to a southerly movement of De la Rey, and three columns converged on Wolmanstaad. The intelligence was defective in the sense that no concentration of Republican forces was occurring, though De la Rey had gone south in order to cross into the Free State and meet Steyn and De Wet, p.159. He left behind him General Kemp, who was situated close to Dixon's camp at Naauwpoort (a few miles south of Olifant's Nek). Kemp took advantage, while Dixon was out clearing farms, to attack him at *Vlakfontein* on 29th May. The attack was made under the shelter of a veldt fire. "Out of the very flames there suddenly burst a torrent of 500 Boers, some firing from horseback, others leading their ponies and firing as they ran.\*" Dixon's mounted men were mainly recruits; before this advance they gave way, but after desperate fighting and heavy losses among the troops the position and guns were saved by the infantry. The loss of horses is unknown: all the artillery animals were killed, and this prevented the enemy removing the captured guns.† Five columns rushed to avenge this attack, but Kemp's forces dissolved. The veterinary officer present at *Vlakfontein* was C.V.S. R. G. Anderson (now Captain A.V.C., T.F.), who was attached to the Scottish Horse. By vigorous measures he was able to save a stampede of the transport, which, parked a short distance from the scene of attack, was suddenly seized with panic and bolted when the shells dropped amongst it.

#### CAPE COLONY.

##### OPERATIONS, MARCH-MAY, 1901.

The expulsion of De Wet from Cape Colony still left Kritzingen to be dealt with. He had been followed as far as the Sneeuw Mountains, which lie midway between Middleburg and Graaf Reinet, but the chase after De Wet had withdrawn all but two of the columns following him (see p.154), those of Gorringer and Herbert, and these held on to his tortuous course. This was devoid of any special objective excepting that of travelling in the line of least resistance, and doing what damage he could to the railway. He was back in the Sneeuw Mountains on 25th February, rode north and disappeared. On 5th March he was found by Gorringer to have travelled south, and was located at Pearston, north-west of Somerset East, towards which he was driven, De Lisle being railed to cut him off. It failed, for Kritzingen crossed the line, and going north through Adelaide got into the Winter Berg

Mountains which he traversed, and pointing in the direction of Burghersdorp crossed the Bamboes Mountains, passed over another line of railway, just west of Stormberg Junction, threatened Burghersdorp, destroyed a British post, captured a supply train, and was at Knaapdar a few miles south of Bethulie on the Orange River at the end of March. During the latter part of this chase the columns of Henniker, Codrington and Crabbe joined in. At Knaapdar he was lost; for 250 miles he had been followed, during which time two mountain ranges had been crossed. It was not until 11th April he was heard of again, when he was found south of Middleburg, where he had united with Fouché, and was chased by Crewe\* who had come from C. Knox. Kritzingen, followed by Crewe, went north, crossed the Orange River, and got into the Free State.† Meanwhile, Scheepers had been leading Grenfell and Parsons an equally fruitless chase in the district lying between Aberdeen and Willowmore.

Scheepers, with whom at this time was Fouché, was chased by Parsons, Scobell and Colenbrander through the districts of Aberdeen, Graaf Reinet, Jansenville, and Somerset East. On 6th there was a fight at Aberdeen with Parsons, on 15th one with Scobell, who, by a 45-mile march prevented the enemy from attacking Jansenville. Malan now joined Scheepers and Fouché, and Scobell attacked and broke up the Commandos on 20th March, causing them heavy loss. Scheepers and Malan hurried to the Camdeboo Mountains, west of Graaf Reinet, followed by Scobell; Fouché made for Pearston followed by Warden, from whom he escaped and joined Kritzingen south of Middleburg, as related above. Scheepers and Malan were not again heard of until the end of April, when they were found in the vicinity of Pearston and driven north by Scobell and Henniker. Lukin, who came out of Cradock, attacked them on the flank, but they doubled back, were chased by Henneker and separated, Malan going north by Cradock, Scheepers making south for Somerset. The latter on his way was attacked by Henneker who had come back by rail, and after being roughly handled escaped in a snowstorm on 12th May, and made for the Camdeboo. Malan meanwhile was chased by Scobell to the west of Cradock; there was a fight on 2nd of May and another on 20th, Malan being driven north in the direction of Maraisburg; here he was saved by meeting the returning Kritzingen, who had re-crossed the Orange River and was making south.

Kritzingen's return across the Orange River on 17th May, with re-inforcements and remounts, was effected in the face of six columns on the south bank and three on the north. He was joined by Fouché who was awaiting him in the Jamestown district. The latter had slipped past Gorringer and

\* Gorringer was refitting. Codrington's column was broken up.

† It can hardly be said he was driven across the Orange River. His visit was voluntary, and connected with recruits and remounts.

\* "Times History," Vol. v., p. 282.

† The last man left uninjured at the guns was the Farrier-Sergeant of the Battery.

Crewe, who now endeavoured to prevent their junction. The two Commandos left the Zuur Berg Mountains, north of Stainsburg, from here they crossed the line south in spite of the 1500 men sent to block them; they then picked up Malan, and the three Commandos marched south. Kritzinger did not get far; marching rapidly Gorringer got to the west of him and Scobell to the east, and he turned east to the Bamboes Mountains.

Since the middle of April Haig had been in charge of the operations in the midland district, it was he who was now chasing Kritzinger with all the columns which could be spared. In the Bamboes Berg Kritzinger was pressed and harassed to such an extent that, leaving Malan behind, he broke away east over the railway in the direction of Jamestown, it was now 29th May. Scobell, strengthened by Lukin, and the 9th Lancers sent by rail from the Free State, closed the eastern outlet from Jamestown; Gorringer, together with a column under Murray from the Orange River near Aliwal, spread out around the north; Crabbe, Wyndham, and Monro (also from the Free State) closed in the west. It was the biggest combination of columns since the De Wet chase of the previous February. Eight columns containing 4600 horses formed one large circle around the invader. He charged through, and on 2nd of June raided and captured Jamestown, where he replenished ammunition, supplies, and obtained remounts. Pursued by Scobell and Gorringer to the north-east, he was surprised and severely handled by Scobell on 6th of June, and escaped on foot; on 7th June Gorringer, together with a column from Aliwal under White (648 horses) attacked him, but he again escaped. Malan, whom he had left behind in the Bamboes Berg, also escaped, but Wyndham, now close to Steynberg, captured some prisoners.

An attempt has been made above to give some notion of the severity of these operations on horses and the numbers employed. A hundred miles of marching are very soon covered in this class of work, even when the actual area of operations, as in the last recorded, is relatively small. Kritzinger's circular course from the Orange River to where he disappeared was not much more than a hundred miles, but that does not represent the distance travelled by the columns which chased him throughout.

The political, as apart from the military, importance of all operations in Cape Colony was enormous, and out of all proportion to the material damage a few wandering bands might inflict. To realise this, it may be mentioned that in Cape Colony alone there were at this time no less than nearly 50,000 troops, regular and irregular, under arms for the repulsion of two or three determined men with a following only numbering hundreds. That being so, it can readily be understood that the capture of these bands could only be effected by the mounted columns; the sparing of horses could meet with no consideration. Night and day, in all weathers, mounted columns travelled over stoney karoo, up

the rugged precipitous sides of mountain 4000 to 5000 feet above sea level, then hustled into the train, bundled out in a few hours, or perhaps two or three days later, saddled up, and once more marching in search of their elusive enemy who probably by now was miles away in an opposite direction.

It is impossible to present any connected account of these operations in Cape Colony, which for eighteen months harassed both the military and political authorities. The "Official History," in referring to this fact, describes the operations as kaleidoscopic. Commandos would combine and threaten, dissolve and scatter to various points of the compass to then unite elsewhere. They had no objective excepting that of making themselves unpleasant, so that military instinct could not divine their next move; there was no scheme, especially at this time, in the Midland district. Later, when a Transvaal General invaded the Colony, Cape Town was the objective, but Kritzinger, Fouché, Scheepers and Malan were satisfied to roam through districts in the heart of the Colony, and in the centre of disloyalty, and succeeded in keeping more than an Army Corps under arms with enormous waste of horses. How that wastage was brought about the above brief account has attempted to explain.

### CAPE COLONY.

#### OPERATIONS IN THE NORTH-WEST,

APRIL-OCTOBER, 1901.

In April, a column under Jeurdwine, 500 strong, had left De Aar for the north-west of the Colony, the old focus of infection, p. 61. On 12th May it was at Brandvlei. In June it had reached Kat Kop, 230 miles due west of De Aar, having patrolled the intervening districts which were in a condition of smouldering rebellion, shadowed the whole way by a force of the enemy under Commandant Conroy. Definite shape was being given to the disloyalty of this distant north-west by one of Scheeper's lieutenants, by name Maritz, a man of remarkable ability and genius for organisation. At present Maritz avoided Jeurdwine as he was not ready, but he marched about the country travelling immense distances. His movements gave Jeurdwine some severe marching in this outlying district of Calvinia, over mountains and dreary sandy wastes which proved most exhausting to his transport. On 8th June Jeurdwine made a forced march of 54 miles in 24 hours against Maritz who disappeared, and after further marching he was obliged to go to Calvinia to rest and refit. In two days he was out again to relieve a post 48 miles west of Calvinia, marching all night through heavy rain he covered the distance in 24 hours and relieved the place. Hearing Maritz was still to the west of him he followed and got in touch on 25th June, but Maritz marched away taking his Burghers on a 200-mile ride; Jeurdwine followed him for days, Maritz travelling from time to time in opposite directions in order to mystify his pursuer.

Jeudwine followed him up to 8th July, on which date he made the almost incredible march of 68 miles, when he handed over the column to Capper. Jeudwine's marches were attended with but little fighting and have not been sufficiently recognised. In 54 days he had marched 1150 miles, an average of over 21 miles a day, "in the face of incredible difficulties of supply, transport and conditions of road." \*

During July Maritz remained in the inaccessible regions of Sutherland. Capper could barely obtain a sight of his bands, which hovered over precipices and heights inaccessible to guns and transport. The position of Maritz at Sutherland, close to the railway and near to Cape Town, was part of a programme. He was waiting for Smuts from the Transvaal. In August he disappeared on one of his long marches, and was next heard of at Van Ryn's Dorp, 40 miles north of Clanwilliam, which he captured on 7th and replenished his stores, ammunition and horses. Capper followed him thither but was late; he then went to Calvinia, and hearing Maritz was in his old haunt at Brandvlei, west of the Zak River, 80 miles north of Calvinia, he adopted the night marching and day resting tactics, found so useful elsewhere, and surrounded the laager, but the enemy galloped through. Capper now did over a 200-mile march to Ceres on the Cape Town railway (65 miles north east of Cape Town), where he arrived on 15th September; until the 15th October his force was employed barring the entrance to the capital against the inroad of Maritz. This leader had largely recruited, and was virtual ruler over the north-western districts; he was now ready to carry out his part of the invasion programme with Smuts, which constituted the entry into Cape Town, but these events will be separately considered. We have been compelled in the interests of the narrative to carry these operations in the dreary desert districts of the north-west, to a point in advance of the general operations.

#### TRANSCAAL.

##### OPERATIONS NORTHERN TRANSCAAL,

MARCH—APRIL, 1901.

While the drive across the Eastern Transvaal, recorded at p. 156, was coming to an end, operations against the north and north-eastern portions, in the area enclosed on the west by the Pietersburg line, and on the south by that to Komati Poort, were being projected. The irregular square over which these operations were conducted had sides each of about 140 miles, and was divided down its centre by a river, the Olifants, which separates the flat bush country on the west from the mountainous area on the east. Hitherto we have seen very little of either of these countries. In Paget's operations through the bush veldt north to Nylstroom in August, 1900, p. 95, the fighting was nearly all in the neighbourhood

of the railway. The only glimpse of the mountainous area was that afforded by Buller's operations to Lydenburg, p. 99. It was now intended to again advance along the Nylstroom line and beyond, and seize Pietersburg, a place which had never yet been visited during the war, and was known to be the seat of great activity. It will be remembered that the occupation of Pietersburg from the north was the objective of the Rhodesian Field Force, and we have seen that it fell through. Pietersburg to Middleburg (Transvaal) form the northern and southern points of the present operations; the eastern and western being indicated by Lydenburg and Nylstroom respectively. From a veterinary point the two areas of bush and mountain divided by the Olifants River are important, as one is a deadly place for horse-sickness during this time of the year, while the other is healthy, though its stupendous mountain ranges of extraordinary grandeur offer a dreadful barrier to animals engaged in military operations.

The operations now undertaken had two objects, the capture of the Transvaal Government, which lived in the mountainous region, together with Viljoen who operated from there against the railway, and the seizure of the enemy's base at Pietersburg. Columns were to be employed operating north from the Delagoa line, driving the Government and the Commandos in the direction of Pietersburg; meanwhile, Pietersburg having been captured was to be used as a base for blocking the drifts over the Olifants River, and so denying escape in a westerly direction to the quarry, which it was hoped would then be compelled to keep moving north where troops would be ready to receive them.

The first step was to be taken by the indefatigable Plumer, whom we last saw with his column in the vicinity of Brandfort on 10th March, after the big chase of De Wet (p. 156). On the 22nd of that month his column was in the train for Pretoria, and on 26th March he left there for Pietersburg. Great economy of animal life was practised by him in utilising the railway for his transport and artillery, and so sparing his animals through the sandy bush country about to be traversed. In spite of the damaged condition of the line two construction trains repaired it as fast as his troops were able to move, while a supply train kept him fed. Pietersburg was occupied on 8th April, and the commando of Beyers disappeared to the East. From Pietersburg he marched S.E. for the Olifants River, in doing so crossing the Strydpoort range of mountains, which separated him from it, through a pass in a solid granite wall only fifty feet wide. There were thirteen drifts to hold on the Olifant's River over a distance of fifty miles, and he was in occupation of them by 10th April. Meanwhile the driving columns from the east were being placed in position. Six were employed working from Middleburg, Belfast, and Lydenburg, the whole under the command of Sir Bindon Blood, who had been brought from India owing to his

\* "Official History," Vol. iv., p. 354.

knowledge of mountain warfare. The six columns had the following strength :

Lydenburg, Lt.-Col. Park	200 horses.
" Maj.-Gen. F. W. Kitchener	550 "
Witklip, Lt.-Col. Douglas	330 "
Belfast, Lt.-Col. Pulteney	750 "
Middleburg, Lt.-Col. Benson	600 "
" Maj.-Gen. Beatson	600 "
	<hr/> 3150 "

The number of mules is not stated, but as there were 6700 fighting men there would be about 2500 mules. The general results of these operations may be briefly stated—both the Government and Viljoen escaped. The latter being in such difficulties that he had to abandon his guns and burn his transport. The Government escaped south before a shot was fired; it crossed the line a little east of Middleburg without difficulty and proceeded to Ermelo. Viljoen awaited results in the vicinity of Roos Senekal, and made no move until 19th April. On 20th four columns were near him, two being within eight miles, yet he eluded both and crossed the Olifants River at a section which had been told off to Beatson, escaping on 22nd April by an unguarded drift, after a 19 hours march. He then deceived his enemy by an intentional march in the wrong direction, finally going south, and incredible as it may appear, camped for several days a few miles north of the line at Balmoral, and from here attacked Beatson in the rear. In the first days of May he crossed the line and joined the Government at Ermelo. These three weeks of activity had produced 55,000 head of stock, munitions of war, and many prisoners and surrenders, but the important persons had escaped.

The marching done in the mountainous districts was very trying. F. W. Kitchener covered 150 miles in the worst part of the country, but the force under Plumer had probably the most trying experience owing to the unhealthy nature of the area in which they were operating. When he arrived at Pretoria on 22nd March, before proceeding to Pietersburg, a new contingent, the 6th New Zealand Mounted Rifles, joined him. They had only arrived on the previous day after a voyage of 48 days from Auckland to East London, and a four days journey to Pretoria by rail.

They were absolutely unfit to take the field; of the 580 horses embarked at Auckland 16 died on the voyage, 57 were unable to leave East London owing to injuries, 13 died in the train on the way to Pretoria, 3 died in camp on arrival there, and 5 were sent to hospital. During the march to Pietersburg they naturally suffered from exhaustion, laminitis, and sore backs, due to the enormous kit carried; catarrh and strangles also appeared. The first case of "horse-sickness" occurred on 4th April, from that time onward cases were frequent. On 12th April the Queensland Imperial Bushmen joined Plumer; they also had just landed in the country and were entrained immediately and sent by rail to Pietersburg; a large number were unshod and many suffering from ship injuries and

pneumonia. About this time cases of glanders were detected among the New Zealand horses. Next to horse-sickness the most formidable trouble was veldt sores and quitor due to the thick thorny bush country in which the force was operating. Twenty per cent. of the entire force was rendered unserviceable from this cause, and many had to be destroyed owing to septic infection.

During Plumer's operations a mobile veterinary hospital was formed at Pienaar's River which received the earlier cases, and a little later a Field Veterinary Hospital was opened at Pietersburg, to which many animals were sent from the columns on the Olifants; the distance, however, was 40 miles, which was against the quitor cases.

The following table shows the wastage in General Plumer's Force, which was of course enormously increased by the two regiments previously mentioned being absolutely unfit to take the field.

Strength on leaving Pretoria	1250 horses
" " " " " " " "	1050 mules
Died or destroyed on march to Pietersburg	49 "
Sent to F.V.H. at Pienaar's River	27 "
Strength on arriving at Pietersburg	2124 animals
Strength of horses on leaving Pietersburg for operations on Oliphant's River, 14th April (Remounts had been received since leaving Pretoria)	1732
Died of Horse Sickness	323
Died, destroyed from other causes	239
Sent to F.V.H., Pietersburg	126
Strength on 6th May on arriving at Silverton, a few miles east of Pretoria (of which 142 are unfit)	893
Loss	839 horses.
Strength of mules on leaving Pietersburg	1145
Casualties on march to Silverton	43
Strength on arrival	1102

We have here a record of 323 cases of horse sickness occurring in a strength of 1732 horses in the space of 22 days (18<sup>th</sup>), as a matter of fact no horse died from the disease after 1st of May, so that there were 323 deaths in 17 days.

The veterinary officers with Plumer's Column were Lieuts. (now Major) W. D. Smith, A.V.D., McLeod, 4th Q.I.B., Tucker 5th Q.I.B., and C.V.S. Glasse. I am indebted to Major Smith for the above statistics.

#### *EASTERN TRANSVAAL.*

##### *OPERATIONS, MAY—AUGUST, 1901.*

In the operations undertaken during the month of May the underlying scheme is not very clear, excepting that from north and south, *i.e.* from the Delagoa and Natal lines, columns were to advance into the interior of the Eastern Transvaal and do all the damage they could. Six columns under Blood started from the northern and three from the southern railway on 13th May, a total of 9,800 horses, and converged on Ermelo, but with no results. The columns then worked independently, Plumer taking in Bethel and then going to Piet

Relief. It was while he was sending in a convoy from Bethel to Standerton that an attack was made on it at *Mooifontein* on 25th May. Harrassed for days it was finally set upon front and rear, and the grass lighted; under the smoke from this charges were made. The only thing which distinguished *Mooifontein* from scores and scores of similar convoy attacks was the heavy losses. This class of work is most severe on transport animals.

An important duty falling to these columns was that of chasing the Transvaal Government; this went on continually for a fortnight, during which time the Government found itself running first into one and then into another column, but always evading capture, and even succeeding in meeting the Free State Government near Standerton. At this meeting the momentous decision was taken of prolonging the war, De la Rey undertaking to invade Cape Colony, the command being given to General Smuts.

The news of *Vlakfontein*, p. 163, took Allenby from the Eastern to the Western Transvaal. Beatson, while marching from the Delagoa railway to Bethel, had a portion of his column surprised at *Wilmansrust* on 12th June and was badly beaten. Three hundred and fifty horses were lost.\* This reverse caused all the columns in the Eastern Command to assemble in the Bethel district, and four of these, including a new Cavalry Brigade under Babington, demonstrated from Bethel as far as the vicinity of Johannesburg, but did no good. During this time Viljoen recrossed the line, and coming in contact with Benson suffered damage.

One of the characteristics of a war of this kind is the rapid change which a few hours may bring about. In a few days the Eastern Transvaal, so recently the scene of excitement, and the hunting ground of several columns, was almost wholly deserted, they having been sent to other areas which had suddenly become the scene of renewed activity. Blood, with his column, passed in July across the line into the N.E. Transvaal, Allenby was called off in June. Six other columns, including that of Plumer, left in July. The Eastern Transvaal was quiet, but the commandos were still there, so was the Government; both required a rest, so went into hiding. One column only remained, that of Benson, whose method of operations caused the maximum of inconvenience and loss to the enemy. With an excellent intelligence system under a local officer, Colonel Wools-Sampson, he substituted night for day raids. Night work for horses is most exhausting, and a high degree of discipline is required to afford them protection from the irregularities which occur in the dark, even under skilful control. As an example of this we may take the apparently

simple subject of "saddling up," an operation never easy even in daylight with a heavy kit, but in the dark it requires the greatest care to ensure that matters are satisfactory. The loose end of a strap is a prolific source of injury, to say nothing of a portion of the impedimenta resting on the spine. Benson, besides being a very fine soldier was an excellent horsemaster; he had been trained in the best school of horsemanship in the Army, *i.e.* in the Artillery. He knew what horses required, and none valued more than he the attention to detail, which is the essence of horse management. With officers and men trained in the care and management of horses, the first step had been taken to put into operation those brilliant military qualifications which unfortunately were so soon to be lost to the Army. Benson's column became the scare of the Eastern Transvaal. Long night marches of thirty and forty miles, and an attack at dawn were his chief weapons, and during the two months of July and August he kept the Republican Forces in a condition of anxious anticipation. Meanwhile Botha, who commanded in this area, though not in evidence, was not idle; he was maturing a scheme which kept him occupied elsewhere, and no reprisals on Benson were at present attempted. His scheme was the invasion of Natal, and formed part of the general programme for the invasion of British Territory, of which Smuts, whom we have yet to see, had already carried out his share in Cape Colony. Ermelo was Botha's point of concentration for this, the second Natal raid, and thither at the end of August the commandos collected.

#### NORTH AND NORTH-EAST TRANSVAAL.

JULY-AUGUST, 1901.

In the north-east Transvaal the columns of Blood and Kitchener worked hard for the next two months with variable success, but the country wore out men and horses. Muller had temporarily taken the place of Viljoen, and gave a good deal of trouble. As usual when tired, the Commandos went into hiding. The columns then returned to their station, or frequently, as we have seen, were sent to some more pressing point. In the northern Transvaal columns under Grenfell, Colenbrander, Wilson and McMicking scoured the district even as far as 60 miles north of Pietersburg. Beyers, who was back in his district, gave them a great deal of work, but for the present there was no indication of his bringing his Commando together.

During the operations under General Blood in the eastern and North-eastern Transvaal further development for the care of the sick in the Field took place. A mobile hospital accompanied his columns and received the sick which were no longer under regimental care. These were driven quietly along in mobs of about 50; three natives under a white superintendent were found sufficient for this number. The animals grazed as they travelled.

\* In this affair, Lieut. Sherlock, Veterinary Officer, Victorian Mounted Rifles, distinguished himself and was mentioned in despatches in the following terms: "At *Wilmansrust* when the doctor was killed he took charge of 40 wounded, and by his skill and attention much alleviated suffering and danger. An excellent officer in his own Department."—*London Gazette*, 20th August, 1901.

The hospital was furnished with transport and was under the care of Lieut. Todd. It moved daily with the supply column, so that the difficulty of feeding animals was lessened. Finally it took up a central position at Carolina, and later at Wonderfontein, receiving not only the sick but the animals captured by columns. The sick were, from time to time, evacuated to the base hospital on the line, which was stationed at Middleburg. The reception of captured stock was disadvantageous from a veterinary point. Possible friction with the Remount Department was prevented by the Veterinary Officer in charge being made Remount Officer for the Columns.

For the northern operations the sick were sent into the hospital formed at Pietersburg.

#### WESTERN TRANSVAAL.

JULY—AUGUST, 1901.

The month of July saw the introduction into the Western Transvaal of a scheme of offence which was destined to assume vast proportions. The readers of this history must have been struck by the rapidity with which an area swept by columns was re-occupied by the enemy, even before the sweeping operations had been brought to a close. Lord Kitchener determined to create artificial obstructions, and for this purpose wire fencing and blockhouses were introduced. These had for some time existed on the railway, at first for the protection of bridges, but latterly for the whole length of the line of rail in exposed districts. It was now part of his scheme to enclose the country in a similar manner, and for the protection of Johannesburg an area of the Western Transvaal was fenced in and defended by the miniature forts. In this way the question of supply was simplified and the risk of capture of convoys and consequent loss of animals greatly reduced. Eighty square miles of the Western Transvaal around the heart of the State were protected by the middle of September.

The military operations in the Western Transvaal, which for two months had not been active, were marked towards the end of August by six columns, employing 6,500 horses, moving against Kemp in the Eastern part of the Zwaartruggen Mountains west of the Magaliesberg. He, however, escaped further west, and in a day or two as Methuen, whose column took part in the above movement, was returning to Zeerust, Kemp attacked him in the valley of the Marico River and caused him heavy loss.

#### CAPE COLONY.

JUNE—AUGUST, 1901.

The enemy without transport or supplies could not have lived a week in Cape Colony had it not been for their friends and sympathisers, who were legion. Nearly the whole Dutch population was disloyal. Among the other absolute essentials to

the existence of a Commando were horses, and these they furnished.

We have seen that in December, 1900, orders were issued for all animals in the affected districts to be brought into military posts, excepting those which could be protected. The result of this order was to produce some 25,000 horses, the majority of which were termed "protected stock," and have been already referred to p. 133. This did not represent by any means the horse population of the districts; nothing was easier than to hide large numbers of animals from the sight of patrols, and these were used by the enemy.

In April an order was issued that all remounts required by the columns operating in the Cape Colony should be obtained from local supply. To meet this several remount depots were opened, the largest being at Cradock, the centre of a horse-breeding district. This tapped a source of supply which had hitherto been largely neglected, for reasons discussed at p. 132. Nevertheless, the fact remains that up to the end of the war horses suitable for Commando were always at the disposal of the enemy. It was this factor which enabled the Republican Forces to roam about the Colony with comparative impunity, as may have been judged from what has already been related of their movements.

Early in June, General French was appointed in command of all the troops operating in the Cape. At this time there were nine mobile columns, an aggregate of 5800 horses. Among these were three regiments of cavalry, 9th, 16th and 17th Lancers, Cape Police, Cape Mounted Rifles, and about 1000 Yeomanry, the latter being very backward in training. \* Gorrings's Defence Force was broken up and newly constituted. Scobell, Crabbe, Crewe, and Monro remained in the Field, Henniker was succeeded by B. Doran, and Wyndham and Lund came on as Column Commanders. The headquarters of General French was established at Middelburg (Cape), and Major Philips, A.V.D., was appointed to his staff as Senior Veterinary Officer.

Kritzinger, who was last seen on 7th June, was located on the 14th trekking South through the Bamboes Mountains, and was followed by Monro and Crabbe in the direction of Tarkastad. Here he was engaged and suffered heavy loss, but escaped towards Cradock, where he captured a patrol on 20th June, which entailed a loss of 60 horses. B. Doran, Scobell, and Crewe endeavoured to close him within the Tandjes Berg Mountains, lying between Cradock and Graaf Reinet, but he escaped north, while Commandant Van Reenen, who was with him, went south. A chase of 200 miles was now carried out by Crabbe, but the commando reached the Bamboes Berg in safety by the end of June. Crabbe had now to refit, and Haig was detailed to look after Van Reenen. Malan was heard of early in June as being in the mountains west of Maraisburg; he moved into those

\* "Times History," Vol. v., p. 312.

south of Middelburg, and was followed by Crewe, by whom he was chased from one point to another of this extremely difficult country. On 23rd June it was found that he had gone north-west to Richmond; this he attacked and inflicted severe loss on the garrison after many hours fighting, but the arrival of Lund on 26th June drove him north-east to Hanover, where he made a stand against Lund, was defeated with loss, and he and his band dispersed.

Scheepers, whose domicile was in the inaccessible mountains to the west of Graaf Reinet, kept B. Doran engaged; in spite of being watched he attacked Willowmore, 70 miles away, on June 1. French determined to surround his stronghold by means of columns, and to send in another to hunt him out. On July 12 the troops were in position, and Scobell had already scored some success, when a gap occurred in the ring and Scheepers broke out on 15th. A party belonging to his Commando had a day or two previously burnt the railway station at Aberdeen, thirty miles south-east. When Scheepers escaped, Malan, recently at Hanover, joined him; they were followed north by Wyndham, who on 19th was still close behind; on 20th Wyndham had to halt for his transport. Scheepers then went west to the Cape Railway, and on the same day attacked and burnt a troop train thirty miles north of Beaufort West, inflicting considerable loss. He then crossed the line and went out into the west, a region where his presence was least desired. A partial recompense for his escape was the scattering of a band under Latigan (a commander who had returned with Kritzingen) by Scobell on the night of the 21st, resulting in many captures including 105 horses.

Kritzingen, who had escaped north from the Tandjes Berg in June did not proceed far, and was located by Crabbe in the middle of July. The latter, while manœuvring to drive Kritzingen south, was ambushed on 21st July at *Jackalsfontein*, east of Witmoss Station (30 miles south of Cradock), and lost 200 horses. Kritzingen was now joined by Theron who had come from the Free State. Fouché remained in the north-east near the Transkei, where he had been obtaining horses and recruits. With him were Myburgh and Erasmus (two more Commandants lately brought across the Orange River by Kritzingen); they had previously been chased by Wyndham in the Molteno district, and now went north to Fouché whom they joined on 7th July. Two mobile columns existed in the north-east, one under Monro at Dordrecht, another under Moore at Aliwal North. Munro accordingly followed Myburgh and Erasmus northwards, and Moore came out of Aliwal to deal with Fouché. On 14th Moore was seriously engaged with Fouché north-east of Jamestown; the action lasted all day, and Moore retired. On 19th, having been re-inforced, he followed the enemy west, and coming into contact there was fighting on 20th and 26th; Fouché finally disappeared over the Orange River on 28th. Myburgh and Erasmus were joined by a

fresh Commando from the Free State, and were attacked by Gorrington on 30th July north of Dordrecht. Gorrington chased them for a week, surrounded the body near Steynsburg and did considerable damage, but the Commando broke through.

These various Commandos had had some experience of the hustling principle which had been inaugurated, and French now considered they were suitably placed for driving tactics to be established. His force was contained within a vast square of the midland district, of which the railway forms three sides. With his eight columns placed at intervals, on a line running from Victoria West—Middelburg—Sterkstroom (from point to point a distance of nearly 200 miles), he marched them south on 30th July over a narrow front so as to enable the various Commandos to get between and behind them. The distance south was 70 miles; it necessitated crossing the mountain range which, under various names, runs transversely across the Cape from Beaufort West to Stutterheim. When south of this range on 3rd August his columns were dispersed from Beaufort West, through Aberdeen to Witmoss and on to Seymour, points 240 miles apart. They then turned about, opened out, and on 6th facing north drove for 100 miles towards the railway connecting De Aar with Stormberg. Scheepers at once broke out south near Aberdeen, and was followed by Alexander and Atherton, but seven Commandos were left between the driving line and the railway.\* There were many fights during these operations. Scobell engaged Lotter and C. J. Botha, Crabbe and Kavanagh were busy with Kritzingen, all on the eastern end of the advancing line. Doran and Wyndham at the western end were dealing with Theron and Smit. The former escaped south, Smit was pressed north, and just west of Middelburg was joined by Lotter and Botha, behind whom was Scobell and Hunter-Weston (a new column commander). B. Doran coming up joined in the pressure and forced the three bodies north against the railway. Smit, however, escaped west, but Lotter and Botha were pressed in to the railway by Hunter-Weston, Scobell, and Kavanagh. Some days prior to this Kritzingen had also found himself against the railway, which was now not only blockhoused but patrolled by armoured trains. These he faced, broke across the line on 10th August, went to Steynsburg, and reached the Zuurberg mountains, where he found the two commandos of Van Reenen and Wessels. Gorrington and Crabbe were in hot pursuit, and driving the three bodies north compelled them after a 50-mile ride to cross the Orange River, inflicting severe loss on Kritzingen on 15th August. Lotter and

\* No sweeping operations could take place until the railway was blockhoused and wired in. This hitherto had not been necessary on the Cape lines. It seems almost beyond belief that a blockhoused barrier, 240 miles in length, was erected in fifteen days. See "Times History," Vol. v., p. 314.

Botha hemmed against the railway boldly attacked it on 16th August but failed; their capture appeared certain. They turned on the converging columns, discovered a gap between them, rushed through in the dark and escaped south to the stronghold in the Tandjes Berg 50 miles away. Followed by Scobell and Kavanagh they were engaged in these mountains, separated and broke away. Scobell with B. Doran, who had just come up, chased Botha to the east, while Lotter remained in the Tandjes Berg, there being no available force to deal with him, Kavanagh having been withdrawn in consequence of news received that Theron was travelling hard from the south. Scobell and Doran wore down C. J. Botha's commando but did not capture the leader. On 30th August they were refitting at Cradock. Smit when he went west made for Britstown followed by Lund, Bentineck, and Wyndham. Wyndham pursued him west of the Cape Town line for over 300 miles during August and the first days of September, finally losing him south of Sutherland.

Scheepers we have seen went south, Alexander and Atherton being in pursuit. He was located south of Uniondale in the middle of August. Alexander attacked him and was driven back with relatively heavy loss.\* Atherton joined in and followed Scheepers, who going west in the direction of Cape Town caused grave anxiety for the stores collected at Swellendam and the remounts at Worcester. Nor was Scheepers now the sole anxiety, Theron reappeared, he was going south from Prince Albert. To deal with him another column had to be sent, and Kavanagh went from Graaf Reinet to Willowmore, and on 2nd September moved against Theron, who was near Oudtshorn.

It was in the early days of September that the first real success was obtained in this exhausting campaign in Cape Colony which had now lasted eight months. Lotter we last saw in the Tandjes Berg. Here on 1st September Scobell made arrangements for dealing with him. It took four days to execute these in such a way as to deceive Lotter. He was in fancied security in a farmhouse near the village of Petersburg, situated in the Tandjes Berg mountains, due east of Graaf Reinet. The farm was rushed just after midnight on 5th September and the whole commando and leader captured after severe loss. Two hundred of his horses were also captured.

The total number of horses engaged in the foregoing operations was 10,500, distributed over eighty-seven columns. Their losses are unknown, but were very severe; this may already have been gathered from the above record of the exhausting work they were called upon to perform. Numerous rest camps were established by General French to which horses were sent before being utterly done up; these were a sound economical measure.

\* It was during this attack that Lieut. (now Major) Carr, A.V.C., was severely wounded and captured.

## *SOUTH-EAST TRANSVAAL.*

### *BOTHA'S MARCH UPON NATAL,*

SEPTEMBER, 1901.

#### *GOUGH'S DISASTER—FORTS ITALA AND PROSPECT.*

It was on 2nd September that General Botha set out from the neighbourhood of Ermelo (p.167) for Piet Retief. His projected invasion of Natal had not been kept secret, it was talked of in Natal itself, and probably regarded as "bluff." Nevertheless, it was considered advisable to strengthen the scattered forces in the area of hostilities by bringing in columns from without; some of these arrived about the middle of August. Pulteney's (late Beatson's) Column from Standerton and the Johannesburg Mounted Rifles under H. K. Stewart went to Utrecht and Dundee respectively, and raiding into the district of Vryheid found no enemy but heard many rumours. Stewart remained at Dundee 8th September, and Colville from Standerton marched north-west in the direction of Amsterdam, thus crossing the road which Botha had already taken south. The latter's progress was delayed by the heavy rains which had set in. Wheeled transport in this extremely difficult country was impossible if speed meant anything, so that Botha's supplies were carried by pack animals. Meanwhile information of his movements was obtained very slowly, but further troops concentrated at Newcastle and South; Gough's Mounted Infantry came from Kroonstad in the Orange Free State, arriving at Dundee on 13th September; Garrett's column from the same State on 6th September and proceeded to Wakkerstroom. In due course Allenby from Pretoria, I. Hamilton from Klerksdorp, and Speirs from Kroonstad followed; Rundle closed the Drakensberg to the west, and Elliot with his strong Division lay on the far side under their slopes, ready to act on either side of the mountain range. Practically all these movements were by rail, a saving in one sense to the animals concerned, though train injuries were both frequent and serious.

Botha was still going south, but the weather had told on his horses which were weak through want of grass which had not yet grown, so that he lost many on the way. Nothing definite was known of his movements until the 14th September, and it was then ascertained that he was marching on Utrecht. Pulteney at Wakkerstroom was the nearest to this point, 28 miles away; the weather was atrocious for wheeled transport, and it took three days to cover 14 miles, while Botha, marching with pack transport, was putting in 11 miles daily. By the 17th he was at Blood River Poort, a few miles east of Vryheid, and within 7 or 8 miles of the nearest point on the Natal frontier, which is here most irregular in configuration.

Gough and Stewart, originally at Dundee, were, on 16th September, at De Jager's Drift across the Buffalo River, on the Dundee-Vryheid road, along which a convoy was expected from Vryheid. To

ensure its safety in the present unsettled state both forces on 17th proceeded along the road, and finally arrived at Blood River Poort and saw a party of the enemy. These off-saddled and turned their horses out to graze, and Gough, determining to benefit by the opportunity thus afforded, swooped down on the incautious party, directing Stewart, a mile or so behind, to follow. As he advanced with his force of three companies of Mounted Infantry and two guns, he was charged by two bodies of the enemy who had been unobserved; the first charge crumpled up his line from right to left, the second one struck him in front. In twenty minutes the whole of the survivors were prisoners, and forty-four were killed or wounded. All the horses, 250 in number, were lost, and the two guns.\* Stewart behind could do no more than save the transport and hold the drift at De Jagers leading to Dundee. The effect of Gough's obliteration was to produce the "sensation" which Botha in a letter previously written to Viljoen anticipated. Clements came from Standerton and took over the forces of Stewart; Pulteney and I. Hamilton then concentrated at De Jager's Drift. Bruce Hamilton was brought from the Free State to direct the columns of Speirs and Allenby, which, since the 23rd, were lying at Vant Drift, 15 miles south of De Jagers, and Botha, without attempting any passage of the Buffalo as it was in flood, went almost due south in the direction of Zululand, and made for a point held by two forts, Itala and Prospect. He moved slowly; it is said his horses had suffered severely from heavy ground and exposure,† and it was 26th September before he reached the forts, 60 miles away from the scene of the disaster to Gough. During these nine days every preparation had been made to defend the positions.

Itala is the only one which interests us. It was held by 300 men of the 5th Division Mounted Infantry, the veterinary officer being C.V. Surgeon Probyn. The horse lines were placed in the centre of an entrenched position, which occupied a level surface at the foot of a long ridge running from Itala Mountain. There was really no fort, but merely open trenches with no cover for the animals. The attack on Itala began at 2 a.m. on 26th Sept. It was not unexpected; the garrison had been warned by Zululand of what was about to occur. What the "Official History" describes as a "whirlwind of bullets" from 1500 rifles opened the fight, the first phase of which ceased just before dawn, but was renewed at daylight with still greater

intensity. From all sides there streamed in a storm of lead so heavy that "it seemed as though the defence must shortly be blown to pieces."\* A ring of fire was poured out for twelve consecutive hours, at the end of which the enemy retired having suffered heavy loss. The British evacuated the position at midnight, leaving 59 wounded behind under the care of C.V. Surgeon Probyn.† Nearly all the horses, 222, of the M.I. were killed.

Meanwhile, *Fort Prospect*, 15 miles away, was attacked for twelve hours, but this place was properly protected, and after a severe struggle the enemy withdrew. Bruce Hamilton at Vant Drift, 48 miles from Itala, started for its relief with 1600 men without transport, and in twenty-three hours reached Itala on 28th Sept., a great but useless march, as Botha was on his way north and the garrison had relieved itself.

The plan to catch Botha in this awkward part of the Transvaal led to a good deal of marching. As a matter of fact he was in a quandary; there was only one outlet to the high veldt available, and this was 100 miles away, but he wriggled past the various columns sent either in pursuit or to cut him off, and emerged from this pocket of the Transvaal unscathed. In this matter of cutting off Botha our forces moved slowly owing to the nature of the country and the use of ox waggons as transport. It was worth a supreme effort to effect the obliteration of this Commando and its gallant chief. Bruce Hamilton, after his march to Itala, turned north and followed, but he was too far behind. W. Kitchener was within ten miles of the enemy, and Clements not more than thirty miles off, but errors and misunderstandings arose and nothing effective resulted. Plumer had been brought from the south of the Free State, but was too late to be of use. Eight columns in all were employed in the endeavour to cut off Botha; it gave the animals an enormous amount of work but with no results. The roads were bad, as evidence of which may be quoted the fact that it took W. Kitchener five days to march twenty-seven miles. Heavy rains and mists made matters extremely difficult; day by day the horses of the various columns became more and more weakened by exposure, and the effects of insufficient food. The escape of Botha from an impossible position was soon to meet with its penalty.

\* "Official History," Vol. iv., p. 220.

\* C.V.S. J. H. Walker (now Agricultural Dept., S.A.) was the veterinary officer with Gough's M.I., and has been good enough to furnish me with notes of this disaster. Gough took the greatest care of his horses; he adopted every expedient to save them and get them in condition. A parade of the sick was held daily, and all his officers, following his example, strove hard for efficiency and reduction of mortality. Especial attention was given to the prevention of saddle injuries. The 250 horses captured by Botha must have been a valuable asset to his force, as they were all in hard condition.

† "Times History," Vol. v., p. 343.

† At the close of the first phase of the fight, the medical officer of the garrison went out to render assistance to the wounded of a party which was outside the defence at the moment of attack. He was captured by the enemy, so that when the second attack was made there was no one to attend the wounded of the garrison, at a time when men were falling rapidly. C.V.S. Probyn, now Captain A.V.C., during the twelve hours this stage of the fight lasted took entire charge of the wounded. For his services on this occasion he was mentioned in Lord Kitchener's despatch of 8th Oct. (*London Gazette*, 3rd Dec., 1901). Colonel Chapman, 5th Mounted Infantry, who commanded in the defence, greatly appreciated the care and skilled attention given to his wounded men, which must have resulted in the saving of much suffering and of many lives.

There were 9000 horses and an unknown number of mules and oxen employed in these operations. The losses were very heavy, but are unrecorded. The names of only a few of the veterinary officers accompanying the columns are known, so that no list can be attempted.

#### *EASTERN TRANSVAAL.*

OCTOBER, 1901.

#### *BAKENLAAGTE.*

Botha arrived at Amsterdam on 11th October, and here received a report of what had occurred in his absence. At present his movements were unknown. Matters in the Eastern Transvaal were in a bad way, for Benson's column (p. 167) had been running riot, and became the fear of the country. All during September he had been dealing heavy blows in the Caroline district, and performing marches which hitherto had never been attempted on an extended scale. For example, on the 10th, 15th, and 16th long night marches brought their reward: on 18th a forty mile ride was followed by a smart attack on a laager and heavy captures. He travelled with a moveable supply depôt, but in spite of all this transport, for the care of which he took infantry, it did not fetter his mobility. The enemy had to conform, and accordingly never spent two consecutive nights in the same laager, and their horses were saddled up before daybreak.

The veil was lifted as to Botha's movements on learning that he was at Athole on 18th October, and two columns brought from the Vaal to Standerton, commanded by Rimington and Rawlinson, were sent against him. Their operations on 25th October nearly resulted in his capture, he fled just in time, leaving his correspondence behind. After some other operations the two columns returned to Standerton to refit.

Meanwhile Benson had refitted at Middleburg, where many of his seasoned and trained men had been exchanged for those who had been doing line of communication work. He left on 20th October with over 900 mounted men, infantry, 230 mule and 120 ox waggons, and about 2300 mules and 1450 oxen. We give these numbers as indicating the amount of impedimenta necessary to enable even a small force to keep the field for several consecutive days. He was now, 30th October, returning to the line for supplies after a not very successful tour. The weather was wet, the drifts difficult, and a high wind blowing in the face of the transport did not help matters. From early morning he had been harassed by the enemy, and by mid-day the forces around him had greatly increased. It is now known that at this moment Botha with reinforcements had arrived. Benson's operations had aroused a feeling of intense irritation on the part of the enemy, and for some days arrangements were being made to deal effectively with him. He was now alone on the high veldt, and the time had arrived. Botha, whose whereabouts was unknown, rode seventy miles, of which

thirty were without drawing rein.\* Some of the commandos joining him had done their sixty miles in twenty-four hours. All were anxious to avenge the losses they had experienced. Benson, now on his way to Middleburg, was the objective.

Benson had been marching since daylight under disadvantageous conditions owing to rain and mist; the enemy was causing some trouble, which increased towards noon. This, though not known at the time, corresponded to the arrival of Botha and the other commandos. A little later some waggons stuck in the mud brought Benson to the spot at a time when pressure was being exercised on the rearguard. The commandos now advanced rapidly, the escort galloped after the guns, which had been sent on, and left the waggons to the enemy. This small force of 280 men of the Scottish Horse and Yorkshire Light Infantry, M.I. and two guns took up position on a ridge, and here the drama was enacted. The ridge was a little more than a mile from the place selected for the camp at Bakenlaagte. At the latter the transport had safely arrived.

In the attack on the ridge the enemy adopted the new galloping tactics. They advanced on it in line, having a front nearly a mile and a half in length; 2000 men galloping, shouting and firing from the saddle soon reached the ridge, where they dismounted and opened fire on the small band. The "Official History"† must tell the story.

"So grand and terrible a spectacle had not been seen, nor had the earth so shaken on any battle field in South Africa. . . . Alone on the gigantic bosom of the veldt the little knot with Benson calmly faced the approaching catastrophe. . . . Flight was still possible, the horses were at hand . . . but no man stirred from his place. . . . In a few minutes a tempest of lead burst at point blank range upon Benson's soldiers. . . . Guinees . . . ordered up the horses to attempt to drag the guns away. The teams were shattered as soon as they appeared on the rise, and not one of their riders rose from the heap. . . . The final scene soon came. When silence told the Boers that resistance was extinguished they rose in five dense rows, poured over the ridge, and swarmed about their handiwork, some still firing furiously, some stripping the corpses, some with unusual ferocity robbing and even shooting the wounded, others hurrying forward to the reverse slope to seize the led horses which stampeding madly, added the thunder of their hoofs to the uproar."

Benson, who was still alive, sent a man who had been stripped of all but his shirt running to the camp and directed his own guns to play upon the ridge where he lay. Shrapnel rained down, and the enemy evacuated the ridge now occupied mainly by the dead and dying. Of 280 men, 66 were killed and 165 wounded. Among those who lived through the fierce fight were the medical and veterinary officers of the Scottish Horse, the latter being C.V.S. C. M. Sharpe (now Agricultural Dept., S.A.), whose horse was killed. Once more, as at Wilmanrust and Itala, the veterinary service was able in a time of great crisis to apply its technical knowledge in the relief of the wounded men.

\* "Times History," Vol. v., p. 367.

† Vol. iv., p. 311.

The losses among the animals were confined to the guns and M.I. horses, the transport animals being in camp; this Botha did not attack. Columns from east and south were soon on their way to the relief of Benson's remnant. G. Hamilton from Standerton with the columns of Allenby and De Lisle, 2000 mounted men, marched 52 miles in the 16½ hours, and Barter near Springs marching through the night covered 30 miles between dusk and dawn. Both columns arrived at Bakenlaagte on 1st November and provide noteworthy examples of forced marches.

#### ORANGE FREE STATE.

OPERATIONS, JULY—DECEMBER, 1901.

#### ELLIOT'S DRIVES—SMUTS INVASION.

QUAGGAFONTEIN, SLANGFONTEIN, TAFEL KOP,  
TWEEFONTEIN.

In the first half of July four columns under Bruce Hamilton continued to harry the south-western and western portion of the Free State, until required to block the driving line for Elliot in operations described below; on the east of the railway, during the same period, C. E. Knox with two columns was raiding Brandford, Thabanchu, Senekal, and Winburg. Immense supplies were obtained by him, among others 16,000 head of stock, and a few days later 70,000 head from districts so frequently "cleared" that it was impossible to believe anything remained. A better example of the difficulty of clearing a country—operations which were the chief source of horse exhaustion now that the enemy would only fight when it suited him—will be given presently, and refers to this identical district.

The news of Smuts projected invasion of Cape Colony (p. 167), led to a fresh distribution of the columns. It was obviously desirable to close the Vaal as soon as possible, and various forces converged on it. Henry and Paris on the western line proceeded to the Hoopstad district. Western left Klerksdorp and proceeded to the Vaal in that section on the direct road to Bothaville. G. Hamilton, also from Klerksdorp, occupied the river lower down, and Elliot, whose division after refitting at Vredefort Road (p. 160) marched N.W., crossed the Vaal, and was at Klerksdorp on 24th July. Meanwhile Smuts, who set out on 15th July, had evaded the columns sent to look for him, and was making for the rendezvous he had appointed for the three other parties who were to join him. Their numbers were small, all four only totalled 340 carefully selected men. The party under Smuts reached the Vaal south of Klerksdorp on 28th July, and while searching for a passage became aware that seven columns were leaving Klerksdorp and marching south. These columns were about to take part in the largest sweeping movement to which the Free State had been subjected. They formed part of a big scheme for clearing the whole of the N.W. part of the State

from the Vaal on the north to the railways east and west and south as far as a line drawn from Bloemfontein to Jacobsdal. The railway lines had been blockhoused and fenced with barbed wire, the southern line—Bloemfontein-Jacobsdal—consisted of constabulary posts, behind which was a second barrier consisting of columns, and again behind this a third barrier of columns extending from Edenburg to Orange River Station. A glance at the map will give some notion of this vast undertaking, the track to be swept was 120 miles long and 100 miles wide.

In addition to the seven driving columns with Elliot there was to be one behind him to prevent the enemy breaking back, and others on his flanks in the advance to keep the enemy from breaking out at the sides. One of these columns was furnished by Plumer, who was placed near Modder River Station, having for the purpose of this "drive" been brought from far off Carolina in the Eastern Transvaal. The total number of columns employed was seventeen, with 13,200 horses, exclusive of transport animals. From the 29th July to the 10th August the "drive" continued, and on the latter day Elliot reached the Modder River. The results, so far as stock was concerned, were good, 186,000 sheep and 21,000 cattle, together with 814 waggons, but the prisoners were few.\*

Smuts and his party were not in the net in which he by accident found himself. With almost unparalleled coolness and audacity he had quietly followed behind Elliot and took advantage, while the latter drew to one side to cross the Modder River, of rushing over, charging through the line of constabulary posts, and after hair breadth escapes from the columns behind this line, he crossed to the west of the blockhoused railway at Jagersfontein Road on 18th August, and reached his next rendezvous at Zastron in the S.E. corner of the Free State. From captures and fire his numbers had been reduced by one hundred men.

Elliot's column on conclusion of the big "drive" faced east, and refitted at Glen. Here with his original force he formed a line between Glen—a few miles north of Bloemfontein—and Ladybrand, points 70 miles apart, and drove on the 18th August in a N.E. direction across the Free State. The idea was to entrap the enemy in the Brandwater Basin where Rundle was waiting to deal with them. Any attempt to break away from Elliot to the north was to be stopped by four columns operating from Winburg and Senekal, but the general results were barren.

Meanwhile, in order to deal with Smuts and his band of stalwarts at Zastron, two columns were detailed and from these he suffered further loss. At Zastron he had met Kritzingen, who had been

\* Elliot reported that the fighting men "he had been unable to capture need not be reckoned with for the future, so little spirit remained in them." "The Official History," Vol. iv., p. 260, adds:—"It will appear later how greatly he undervalued, not only the numbers, but the quality of the game which had escaped him."

driven out of Cape Colony in operations yet to be noticed. Untiring efforts were made to surround these two dauntless men with their following of 500, and for this purpose four more columns were poured into this area, one coming from as far off as the Magaliesberg. Fifteen miles away was the Orange River: it was held by Hart with three columns, two garrisons, and a line of blockhouses; nevertheless Smuts crossed on 4th September with small loss, Kritzingers remaining behind to keep the columns employed, and then disappearing into space. The next time that Smuts crossed the Orange River was as a Peace delegate.

The "Official History of the War," after remarking on the almost unaccountable failure of the British combination to stop this leader's progress, adds, "Throughout the campaign in South Africa there was scarcely a more striking feat of perseverance, daring and good fortune, than Smuts' ride of 300 miles, through one British army after another from the Gatsrand up to and over the banks of the Orange River." \*

The "Official History," † in commenting on the disastrous escape of Smuts, ‡ from what appeared to be an impossible position on the north bank of the Orange River, points out that the investing columns so exhausted themselves by skirmishing, that at the critical moment they had to pull into the railway to refit. It attributes this to the neglect to appoint a single and supreme commander on the scene of action. §

\* "Official History," Vol. iv., p. 268.

† Vol. iv., p. 267.

‡ It was due to his influence, and above all his strong personality, that Cape Colony for the remainder of the campaign was never free from Commandos. It was Smuts who actually organised, and very nearly succeeded in carrying the war into the streets of Cape Town. Young, bold, vigorous and eloquent, he was a natural military commander with no training in the science of war—for by profession he was a lawyer—and nearly succeeded where Botha, De la Rey and De Wet failed. His military skill stands out even in such a body as the Republican Forces, where almost every man was potentially a General.

§ It may seem a far cry from military operations to veterinary organisation, but the criticism above made holds equally well. It is impossible for one man centrally situated to control the hundred ramifications of such an intricate and widely-spread machine as was employed in this campaign. When the authorities were begged to create administrative veterinary officers from the lower ranks by giving them temporary appointments, it was refused as unnecessary. Yet, in no other way is it possible to co-ordinate the work of the large body of executive than by the control and supervision of a staff of administrators. It is economical from every point of view, the work is equally distributed, local difficulties met which cannot brook delay by reference to headquarters, and machinery kept moving. In this way exigencies are met as they arise, and not a few hours hence when it is too late to be of any use, while the work of officers and care of the sick are properly supervised. A body of executive officers without administrative control on the spot, or within reasonable distance, is like a flock of sheep without a shepherd. If this is the case where the whole personnel is trained for war, it can be imagined how much more necessary administrative control becomes, when five-sixths of the staff are civilians without any previous military experience or training.

While Kritzingers was lying in the neighbourhood of Zastron he was surrounded by no less than seven columns, two under Plumer, two under Thorneycroft, and one each Rawlinson, Basing and Damant, yet he, with other small bodies of the enemy under Brand, were able to defy capture and even to raid the district.\* About the 16th September they parted, Kritzingers going south to the Orange River, where at *Quaggafontein* on 20th he destroyed a party of Lovat's Scouts, while Brand went north, and on 19th September captured at *Slangfontein*, near Sannah's Post, a small force of 170 M.I., Constabulary and two guns, which was out on a raiding expedition. All the horses were lost.

Strange to say Kritzingers did not cross the river after Quaggafontein, though it was open to him; he returned to his hiding place with the captured horses, rifles and ammunition, when by chance Thorneycroft ran into him and inflicted punishment, though Kritzingers was not included. Plumer near at hand could have taken up the matter but for the fact that he was suddenly called to the neighbourhood of Sannah's Post in order to deal with Brand's Commandos, which had captured the M.I. and guns. Thither also Rochford from the western side of the railway had despatched six columns, but nothing resulted, the Commando had vaporized. Plumer, however, made another march south on 27th September, passing down the left bank of the Caledon with Du Moulin's column, where he had a skirmish on 1st October. He reached the railway at Springfontein, and was soon in the train being hurried to the south-east part of the Transvaal in connection with Botha's invasion.

Elliot's visit to the Brandwater Basin, referred to above, resulted in the capture of 100,000 head of stock, which were taken to Winburg 6th September, together with vehicles, and the destruction of 850 tons of wheat. On 8th September he made another march east; the clearance now made was still greater, and on 17th he was directed on Bethlehem in consequence of Botha's raid. Elliot arrived at Bethlehem on 22nd, and reached Harrismith on 26th September with 60,000 head of stock, waggons and agricultural produce. He now lost Bethune who was required in Natal, and Speir's column, while that of Dartnell, operating in the Harrismith district, was also withdrawn to Natal. Elliot's duty was to watch the Drakenberg until the Botha raid died out.

Rimington continued through September carrying out the class of operation noted as taking place in August. One of his journeys was to surprise De Wet and Steyn between Heilbron and Frankfort. In quest of them he performed long and rapid marches; on 23rd he marched 48 miles and made

\* Later on Damant went north to guard the construction of the Heilbron-Frankfort blockhouse line, Plumer went into the S.E. corner of the Eastern Transvaal, but four other columns were brought in which operated under Knox from central entrenched camps, and cleared the district of supplies.

many captures, but not those most desired; on 24th he rode 57 miles during the night and surrounded a house in which De Wet was supposed to be lying ill. The "Official History" draws attention to the fact that these forays could scarcely have been equalled by the enemy.

The other operations in the Free State during this time were largely suspended in consequence of Botha's descent on Natal. Elliot remained, but was guarding the Drakenberg; De Lisle and Broadwood were not entirely idle, but their operations were small. In Rundle's area some work was accomplished by a column under Briggs, who in return was attacked by De Wet, by the new method of charging, and narrowly escaped destruction. The fact was that Rundle's three mobile columns were very weak in mounted troops. He had at Harrismith a considerable number of Yeomanry who were in the stage of elementary instruction.\* These men knew nothing of the care and management of horses and appeared disinclined to learn. They used up animals in their training at a rate with which it was impossible to cope; they neglected the horses which were under their care, and though they possessed some self-sacrificing veterinary officers of considerable ability, their task was rendered entirely unprofitable for want of higher support.

In September, Bruce Hamilton having gone to the Natal border, his columns became scattered. Byng and Dawkins went to guard the construction of a block-house line running south from Poteschefstroom into the Free State, and during this month had many successful night raids. It was again observed how trifling was the effect of the passage of a clearing column unless it remained in the district and systematically devastated a given area. Byng found that places in the path of Elliot's big drive were once more in occupation and even replenished, though but a month previously they had been swept over by his numerous columns. Elliot himself found at his second visit to the Brandwater Basin, that farms which had been cleared were again replenished; as the "Official History" remarks † "No resources are so difficult to dry up as those of an agricultural people." It was recognised that something more than "drives" were required to clear a district.

To meet this, columns were no longer to sweep districts which formed important sources of supply, but were to remain in them and clear a definite area "of every living creature." ‡ Ten columns

\* The "Times History," Vol. v., p. 432, says:—"There were 3,000 untrained Yeomanry sent him in April, and the majority of the officers, with 20 per cent. of the men, were sent home as useless."

† Vol. iv., p. 325.

‡ On 11th July, 1901, an Order was published in which it was pointed out that the speedy termination of the campaign depended on the relative horse supply of our own and the enemy's troops. It was there stated that the enemy was reduced to riding mares and young stock, and to prevent this column commanders were directed to collect

under C. Knox now took up the "fixed area" scheme in the region north of the Orange River in the south-east corner of the State, and remained there two months. Fighting and raiding went on day by day; it was then realised the enormous difficulty of clearing even a small portion of the enemy's country. Sufficient grain was found "concealed in false ceilings and by false walls to feed the Boer forces in the district for years.\* Further, several Commandos of between 200 and 300 strong were unearthed, though the district had previously been scoured by columns scores of times. The continuous work which all this represented for the horses need not be further pressed.

Elliot's guard of the Drakenberg was not an idle time; before the end of October 26,000 head of stock had been collected and many waggons.

Rimington had passed into the Eastern Transvaal in October, and his place in the Heilbron district taken by Wilson and Damant, the latter guarding the block-house line being constructed to Frankfort. Fighting around Heilbron now occurred, although the district was believed to be empty. Wilson was attacked and a party ambushed; Damant had a strong Commando around him, and 1500 were known to be near Heilbron. These were attacked by Damant and dispersed, but the presence of such large bodies of the enemy was indicative of some preparation for reprisals. De Wet had long been silent, but towards the end of October it was known that his Commandos were assembling on the Liebenbergs Vlei River, 45 miles south-east of Heilbron, and a plan was made to surround him; "unlimited ingenuity and thought were lavished on the scheme." † Briefly, it consisted of a ring having a diameter of 150 miles. Thirteen columns, containing 15,000 horses, were thus employed, and on 6th Nov. the contraction of the ring was effected in six marches. It led to 14,000 head of stock, 200 waggons and a batch of prisoners, but no large body of the enemy was within the circle. The information of the convergence had been flashed by heliograph from hill to hill, and the Commandos had marched out while the gaps in the circle were still wide. ‡ The columns now dispersed, and two of them were attacked on 16th Nov. when near Heilbron, evidence that the enemy was still in being.

and destroy at once all such animals which were useless as remounts. This is the Order referred to in connection with Elliot's column at p. 161.

The Order goes on to say that to clear the country of horses is essential to peace and its subsequent maintenance, and that it is impressed upon all commanders "that there must be no hesitation about destroying useless horses and young stock on the ground that they can be of no use to the Boers, cost nothing to feed, and that it is a pity to destroy them. That they should eventually grow up to carry an armed Boer to the disturbance of the public peace is exactly what it is desired to prevent."

\* "Official History," Vol. iv., p. 328.

† Idem, p. 331.

‡ Idem, p. 333.

During the remainder of November Rimington and Damant raided, the former sometimes north of the Vaal in the vicinity of Greylingstad, sometimes south. Elliot also made another drive; leaving Harrismith on 19th Nov. he worked by Bethlehem and Lindley to Kroonstad. At Lindley, without knowing it, he passed close to De Wet who was awaiting a Council of War. As far as Bethlehem he was supported by Rundle and Dartnell. There was constant skirmishing, and when he entered Kroonstad on 30th Nov. he brought with him 42,000 head of stock and many waggons. Rimington, a day or two before this, had suddenly descended south from Frankfort in consequence of news regarding De Wet being between Reitz and Lindley holding the above-mentioned Council of War. He made for the point with Wilson and ran into a hornets' nest, De Wet was present with several Commandos. Rimington's transport, some miles behind, was attacked, and was only rescued with difficulty and the attack driven off. But De Wet coming up with superior forces arranged to cut Rimington off from Lindley, which was only five miles away. A severe storm delayed his arrangements. During the night Rimington stole away in the opposite direction to Heilbron, and saved himself the fate of Benson. Next day De Wet entered Lindley; it was evident that after the long period of eight months since his retreat from Cape Colony he had once more opened another and, as it proved, his last campaign.

In consequence of the recrudescence of the noted leader another drive was planned, in which the impression to be conveyed to the enemy was that it was to take place in an easterly direction, but on a given date all the columns were to double back, drive to the west, and so enclose the Commandos which it was hoped would have passed from east to west for safety.

Again we must realise the nature of this gigantic undertaking. Elliot with his columns was to march east from Kroonstad on December 8th. Rimington and Wilson were to leave Heilbron and join Damant at Frankfort, and move to the line of the Liebensbergs Vlei, which runs south to north immediately to the east of Bethlehem, Reitz and Frankfort. This movement was effected by 11th Dec. Meanwhile, it was known that De Wet was south of the line of drive, having collided with one of Elliot's columns on the first day's march from Kroonstad, nevertheless the columns now faced about, and for four days drove west towards the railway. The results were trifling, the real objective of the operations was 40 miles south awaiting the dispersal of the columns and organising his forces which were daily growing in strength. But the columns did not disperse, on the other hand five\* converged on the very place he had recently occupied, but they saw nothing of the enemy nor did they all see each other. They returned to their bases, Elliot proceeding to Kroonstad after six weeks continuous operations. De Wet, on the other hand, was

well informed; he was now north of Bethlehem awaiting the return of the Harrismith column under Dartnell. This latter he ambushed on the 18th only eight miles from Bethlehem, and fortunately failed. He had to deal with the Imperial Light Horse, whose experience dated from the first day of the war.

After Elliot's last drive, Rimington and Damant returned to Frankfort, where they again worked in conjunction protecting the block-house line then under construction from Frankfort to Vrede. Here on 20th Dec. at *Tafel Kop* Damant met with almost complete extermination of a portion of his force, due to the enemy posing as Yeomanry and advancing to point blank range before being discovered. It was a repetition of Bakenlaagte in the devotion shown to save the guns, seventy-seven men out of a total of eighty being killed or wounded. All the horses were lost so that the guns could not be carried away by the enemy, and meanwhile reinforcements, including Rimington, completely turned the tables on the victors.

De Wet after *Tafelkop* lay near to the block-house line running from Harrismith to Bethlehem, in the difficult Langberg hills, collecting his Commandos, now 1200 strong, though at this time the local Intelligence Department reported the existence of 70 in the neighbourhood. Nine miles west of Elands River Bridge, itself 18 miles west of Harrismith, a party of the 11th Batt. Imperial Yeomanry, 500 strong, was safeguarding the construction of the line, their camp being on a hill at *Tweefontein*.† It was Christmas Eve, and since the 21st Dec. the hill had been occupied. During this time it had twice been personally reconnoitred by De Wet. He had marked down the troops on this lonely hill for destruction, and no better night could be selected than Christmas Eve. The men were in tents and the horses picketed a short distance away. At 2 a.m. on Christmas day the camp was suddenly attacked, the enemy was actually in it before being discovered, and swept the place with fire. They then charged down the hill on to the tents and horse lines shouting and shooting. In an hour the work of destruction was completed and the looting began. 145 men were killed and wounded, 200 taken prisoners. All the horses were lost, killed or captured. The Kafir transport drivers with the column were shot out of hand. The Burghers made a good Christmas breakfast, and then left with guns, waggons, and loot at 4 a.m. A messenger to Elands River Bridge for help did the thirteen miles under the hour, and the Imperial Light Horse galloped out, but were unable to pursue the enemy who had already vanished into the hills of the Langsberg. On the 25th, De Wet marched north, and leaving his force, in order to visit Steyn, directed his Commandos under Prinsloo to keep between Reitz and Heilbron.

\* Three from Kaalfontein (between Lindley and Kroonstad), one from Winburg, and another from Harrismith.

† We have adopted the official name, the hill was Groen Kop.

Meanwhile, Elliott at Lindley had been directed to march on Reitz, and left Kroonstad on 26th Dec. His force of 2000 men was now in two columns, one under De Lisle, the other R. Fanshawe. On 28th, Elliot came in contact with Prinsloo's force, but was outwitted by the Republican General who escaped north. Contact was again obtained, but was lost at night after a remarkable march by Elliot of 70 miles. To accomplish this, half of Elliot's force marched east without guns or transport. De Wet rejoined his force passed to the east, where he dispersed his Commandos, while Elliot went to Lindley for supplies.

The number of columns engaged in these operations in the Orange Free State was between 30 and 40. During July and August there were 37 columns employing 23,200 horses, exclusive of transport animals. From September to November there were no less than 43 columns with an aggregate strength of 27,400 horses. Such was the work being carried on in only one of the three areas of warfare.

Commenting on the extraordinary inability of the British Forces to bring about a decisive action when the enemy was massed, or to prevent, almost under the eye of the columns, concentrations for the destruction of isolated detachments, the "Times History" \* reviews the position of affairs which, though in the main a military criticism of the methods adopted, is so intimately connected with the wear and tear of horses, that we cannot do better than reproduce it.

"The operations described in this chapter may be said to mark the final failure of the standard British measures. To have proceeded on the same lines would have been to permit an indefinite extension of the war. The waste of energy had been enormous. If the reader will reckon up the troops and horses employed, and the distances covered by the columns in the north-eastern Free State during the last two months of 1901; if he will consider the fruits of their labours, which, if we except the deaths of Haasbrock and Olivier, and the burghers slain at Tweefontein, was represented only by dribblets of killed, wounded and prisoners, and by damage to crops and stock; if he will then reflect that De Wet, having concentrated undisturbed in the midst of these movements, scarcely moved outside the small triangle, Lindley-Reitz-Tweefontein, thus husbanding his men, horses and ammunition; if the reader will make this comparison, he will understand how it was that British leaders and their troops, under the incessant strain of ineffectual marching, were liable to lose ardour and tackling power, while the supply of horses was never equal to the demand; and how it was that the Boers, in the forlorn condition of their country, retained the power to deliver such strokes as at Tafel Kop and Tweefontein."

The only part of this criticism that we would venture to expand is that dealing with the horses. The supply of horses was equal to the demand, but the supply of *conditioned* horses never was—and never could be under the system adopted of issuing them to columns the moment they had been imported. We have throughout this narrative quoted the captures of stock made by the various sweeping operations as far as they are recorded. It is not

always easy to distinguish between horses and cattle, but it is known that many thousands of horses were brought in from the Free State operations alone during 1901. We have given evidence p. 160 of the proportion of these fit for military purposes, and it is true that very many were so employed. But was this source of supply fully utilized? Thousands of suitable animals had never been handled; it did not appear to occur to the authorities that unbroken horses require training, and the more mature they are the more difficult this becomes. Where was the staff to come from for this work? Rimington\* and De Lisle trained unbroken horses with their columns, the latter placed them in the ranks at the rate of three or four † a day. Besides being a first class horse master and enthusiast, he was fortunate in possessing a body of Australian horsemen in his column to whom the handling of unbroken and troublesome horses is a pastime. But all columns were not so favourably placed, nor, unfortunately, did all possess leaders with so keen an eye to possibilities and a knowledge of how to turn them to the best account as were to be found in Rimington and De Lisle. But apart from the local supply, who was to condition the imported horse? He certainly could not be made fit for work by remaining a month in a remount depot before issue, a restriction urged on Lord Kitchener from home. ‡ He required to be ridden, and for this purpose the existing staff at Remount Depots was wholly insufficient and untrained. The only people who could have trained these horses for the field were the 11,000 cavalymen employed by the various columns, and unless hostilities could be suspended for six or eight weeks so as to have allowed some thousands of horses to be made fit for work, it was impossible by any less drastic measures to have coped with the question of fit versus unfit animals †

## CAPE COLONY.

SEPTEMBER—OCTOBER, 1901.

### MODDERFONTEIN.

Smuts, whose early adventures have been alluded to at p. 173 crossed the Orange River on 4th Sept. in the vicinity of Aliwal North, and made south-east in the direction of Jamestown; with him was Fouché. He was pursued, but unsuccessfully. His entry into the Colony was part of a bold scheme for capturing Cape Town and Port Elizabeth, the latter being Smuts first objective, though

\* R.C. Erid., Q. 12,606.

† I quote from memory, being unable to find the reference.

‡ Cd. 963. Cables 8th Jan., 21st Nov., 7th Dec.

† It may be suggested that Kaffirs could have conditioned the riding horses, but such a system would have taken a good deal of organisation. If the thing was to be done rapidly the Cavalry with the columns appears the best solution, especially as they possessed the saddlery, an important point which would have delayed any system worked by Kaffir labour.

circumstances compelled him to pass to the west. The chase of Smuts, whose journey began under such dramatic circumstances, is only of interest to us as enabling an idea to be formed of the nature of the work expected from the horses. It is necessary to indicate what he did and where he went if we are to appreciate the work demanded from the animals, and the distances covered by the twenty columns, with its 9300 horses, which endeavoured to arrest his progress.

Six columns were already within the area selected by him for invasion; these were so disposed as to keep him to the east, and deny the midland district which had only recently been swept, p.169. In spite of the collection of columns Smuts was able, after a twelve hours fight on 10th Sept., to wriggle between Monro and Doran in the dark, and then pushing on all night through heavy rain, did not halt until he had crossed the Eastern line in a south-westerly direction, and placed forty miles between his commando and that of the enemy. Four columns were told off in pursuit, and these were pushed on both by road and rail, in order to plant forces in his path in the direction in which it was anticipated he would take. One of the forces, consisting of a squadron of 17th Lancers 130 strong, was attacked by Smuts on 17th Sept. at *Modderfontein* on the Elands River, north of Takastad, and decimated. Half the horses of this squadron were captured, the other half were killed in action. The columns of Doran and Gorringe once more closed in, while Smuts travelled up and down the country in the space enclosed between the Eastern and Midland railway, the columns at his heels. Sometimes he was turned, and when almost hemmed in would find a line of escape between his pursuers. This he did on the 9th, and rapidly travelling south for the Winterberg Mountains found his passage barred. He came back going west in the direction of Cradock and ran into Scobell. He was then chased south, and being guided over the mountains in the dark saved his commando. It cost him 100 horses, but of these he had ample, owing to his captures at *Modderfontein*.

After crossing the Winterberg he rapidly made for Adelaide, was turned aside by local forces, and still pressing west crossed the Midland line. On 30th Sept. Gorringe, who was in hot pursuit, made contact in the Zuurberg Mountains north of Port Elizabeth, but not for long, for Smuts turned south in the direction of that city. French now threw more columns into the next line of rail west, which runs from Port Elizabeth to Graaf Reinet, so as to be able to stop further progress in that direction. Meanwhile Smuts turned north, being so harassed that he divided his Commando, one portion under Venter going towards Somerset East, while the main body crossed the Graaf Reinet line, in spite of the troops sent by rail to forestall him. Scobell on 8th Oct. now took up the pursuit, and for four days with barely any rest day or night he followed but could not overtake him. On 16th Smuts, still going

west, in the direction of the main Cape Town line, met Scheeper's late Commando and the two travelled together; by this time Scobell had to go to the line for supplies, and Crabbe took up the chase. The general direction now taken by Smuts was south into the valley of the Olifants River; he then went west, Crabbe, who was still in pursuit, moved towards Oudtshoorn where he linked up with Kavanagh's column from Ladysmith, and during the last week in October endeavoured to surround Smuts. But the latter succeeded in working west, crossed the Cape Town line at Constable on 31st Oct., and made for Sutherland. He had succeeded, in spite of opposition, in reaching his objective after a remarkable chase of not less than 600 miles.

Venter, who broke away in the direction of Somerset East, was chased by B. Doran and Lukin; the latter had now taken over Gorringe's column. Venter's position on exhausted horses was desperate, but he boldly broke through a line of local troops between Somerset East and Pearston and took them prisoners. Thus remounted and re-equipped he proceeded north. The Midland and Graaf Reinet lines were used to hurry troops forward to cut him off, thereupon he doubled back and crossed the former line between Middelburg and Graaf Reinet. Nevertheless, Lukin overhauled him at New Bethesda, where the Commando was attacked with loss. It then broke away north-west, and was again found on 26th Oct. south of Richmond. Scobell at this moment was on the western line refitting; he was at once sent to Victoria West Road to cut him off, but Venter crossed the line and escaped to the west. Before he crossed two commandants left him to go south. These were Malan and Hugo, the latter the Free State judge; both were dangerous and determined leaders. B. Doran followed them in the direction of Willowmore. The pair had previously been joined by an equally dangerous man Latigan, whose Commando we saw, at p.169, had been dispersed by Lukin on 21st July. B. Doran located his enemy forty miles west of Willowmore where he attacked them. Doran was wounded and his horse killed. His place was taken by his brother W. Doran, who chased the trio north-west, but they all crossed the railway above Fraserburg Road station on 13th Nov., and went out into the west towards Sutherland.

When Theron went south after appearing at Prince Albert on 2nd Sept. (p.170), he made for Oudtshoorn, Kavanagh from Willowmore moved in that direction. Theron then made for Mossel Bay, and when within a few miles of this port Kavanagh caught him and drove him west across the Gouritz River. Here Theron lost over fifty horses and several men. Still keeping west and well ahead of Kavanagh he attacked Heidelberg near Riversdale on 13th, the garrison of which kept him employed until Kavanagh came up, when he made off north-west for Barrydale. When Kavanagh reached this place on 17th, the chase was temporarily dropped as he had to go into Swellendam for supplies.

It is noteworthy that at Barrydale Theron was only 130 miles from Cape Town. It is fortunate Kavanagh prevented him from reaching the sea at Mossel Bay, as the moral effect of this would have been very great. After Kavanagh fell out, Alexander and then Wyndham endeavoured to intercept Theron, but he crossed the Cape Town line at Touws River on 22nd Sept., and went westward into the Sutherland district.

Scheepers remains to be dealt with. It will be remembered that he repulsed Alexander on 19th August at Uniondale, p.170. From here he went west, his head being turned towards Cape Town. Making for Ladysmith on 23rd August he was twice caught up but forged ahead, and caused much anxiety by making for Swellendam, with its large collection of stores, or even for Worcester where thousands of remounts existed. By 9th September Scheepers was headed from the Cape Town line and divided his Commando; part under him made for Swellendam with Atherton in pursuit, the other, under a boy Commandant, Van der Merve, went north, and almost immediately encountered Crabbe from Laingsburg; Crabbe destroyed the Commando, including its Commandant, on 10th. Crabbe was now able to join Atherton in chasing Scheepers. The latter arrived at Ladysmith on 12th, and while Atherton operated around Oudtshoorn to prevent a break away north, Crabbe kept Scheepers in the difficult country on both banks of the Olifants River, where for days he twisted and turned in order to avoid not only Crabbe and Atherton, but also Alexander, Wyndham and Kavanagh, who by this time were available to act against Scheepers in consequence of the escape of Theron. Scheepers, working north-west, "strove like an imprisoned panther to break through the cage of troops and precipices which held him in." \* On 5th October Atherton was able to push him towards Kavanagh, who robbed him of sixteen men and forty horses; still running north from Matjesfontein he lost 150 more horses, and on 8th sixty more. By the time he reached the Wittebergen Mountains, south of Matjesfontein, he had only fifty or sixty mounted men left. By now Wyndham, Kavanagh and Atherton had dropped out, and only Crabbe and Alexander remained. Alexander followed him across the line, Crabbe took train for Beaufort West, with the intention of coming on him from the north, but Scheepers course was run. Sick with fever he was captured in his bed on 11th Oct. His Commando being led by Pypers, who subsequently joined Smuts. †

\* "Official History," Vol. iv., p. 284.

† Scheepers being a rebel was shot four months later. He was described by one who fell into his hands \* as a young and superior man, who wore a semi-military uniform. His men were distinguished by wearing yellow puggaries. It is interesting to learn the actual life led by these men on Commando, and the methods they followed which enabled them to evade pursuit. An account of this is given in the

"Rhodesia and After," S. H. Gilbert, 61st Squad. I. Y., 1901.

## WESTERN TRANSVAAL.

SEPTEMBER—OCTOBER, 1901.

MOEDWIL, KLEINFONTEIN.

The events recorded in the last section had helped to deplete the Western Transvaal of troops; G. Hamilton, Allenby and Garratt were now in the Eastern Transvaal; Methuen was refitting at Mafeking after the affair on the Marico River, p.168; Featherstonhaugh's columns, led by J. Williams and Hickie, were doing the same at Ventersdorp after two ineffectual attempts on Kemp. Kekewich had now taken over command of the force in the entrenched camp of Naauwpoort, lying south of Olifants Nek, and on 13th Sept. with a force of 560 mounted men, consisting of the 1st Scottish Horse, 7th Batt. I.Y., Infantry and guns, he moved along the northern slopes of the Magaliesberg, engaged in the never-ending work of clearing the country. After some days he passed through Magato's Nek, and was now in the difficult and ever-dangerous Zwarttruggens. When seven miles east of the pass he encamped on the Selous River at *Moedwil*. Nothing had been seen of the enemy, and though this was the haunt of De la Rey, he was believed to be away.

The camp of Kekewich was attacked before dawn on 30th Sept. by 1500 men under De la Rey and Kemp, who had followed the Column for a week until, presumably, its position was suitable for their operations. Considering the circumstances and that many irregular troops were receiving their baptism of fire, there was very little confusion at the moment of attack, in spite of the fact that "mobs of terrified horses and mules stampeded wildly through the camp." The fire was very heavy. "Horses and mules went down in hundreds, and a number stampeded in the direction of Megato Nek. † Very soon after daylight Kekewich was

above quoted work by one who spent eleven days as a prisoner with Scheepers. Their camp at this time was at a farmhouse in the Camdeboo Mountains, situated in a ravine at the foot of almost precipitous masses of rock. The Commando was made up of old and young, some being boys of fifteen. In the evening they sang hymns; it may be remarked that these performances are not inspiring. It is the old Puritan drawl, the notes being prolonged in such a way as to render identification of the air almost impossible. When the Commando broke camp the men assembled, and bare-headed sang the Transvaal National Hymn. This was always done unless pressed by the enemy. The following gives a very clear account of how a Commando moved in a difficult country:—"They had no transport, and dismounting they tied their horses in long strings head to tail, with an old stager in front. The animals then clambered up the almost perpendicular rocks by a dizzy track, which the Englishman would have thought twice about attempting on foot. The Boers clambered after them, sometimes having to use their hands as well as their feet, and so the summit was reached." When the men had no food they lived on the leaves of the "Spek-boom" tree, which furnishes fleshy leaves tasting like sorrel. It is little wonder that an enemy so resourceful and self-contained could move about a friendly country with relative impunity.

\* "Times History," Vol. v., p. 381.

† Idem.

able to do more than hold his own, he made a counter attack, and so threatened the left flank of the enemy that they shortly retired. The losses were 192 men, while 512 horses and mules were killed. It was impossible for Kekewich to pursue as "there was scarcely one unmounted horse in camp.\*

Featherstonhaugh had been advancing north with his Columns from Ventersdorp, and being 25 miles south could hear the firing at Moedwil. The Columns under him searched for De la Rey, but he was invisible. Meanwhile, Kekewich proceeded to Rustenburg to refit. In twenty-four hours after Moedwil he had received 320 horses and 200 mules,† and on the 13th Oct. was marching west with a new force in search of his late antagonist in conjunction with Methuen, who was advancing from Mafeking via Zeerust to meet him. The two Forces met and saw nothing of the enemy. Each therefore turned about and retraced its steps.

Methuen's way back led through the heart of De la Rey's reserves. It was known to be a most difficult and dangerous road, and especially prone to attack. The force was in two columns twelve miles apart. On the 24th October, the southern column was ambushed at *Kleinfontein* by a party of 600 men concealed in a belt of timber. With this southern column were 680 mounted troops of the 5th I.Y., guns and Infantry under Von Donop, together with a train of 100 ox and mule waggons. The Force being engaged in front, the 600 men in hiding then rode out of the wood in three divisions "like a regiment of European Cavalry,"‡ and cut the long train into three portions. While some attempted to divert the waggons by shooting the unwilling drivers, others made for the guns with the rear guard where a struggle occurred. The waggons in the rear were now being driven off by the enemy, twenty had been overturned, and dense bush prevented the passage of others, but the guns with the convoy and the efforts of the Imperial Yeomanry had turned the tide, and in half-an-hour the affair was over. It cost 84 men, half the Yeomanry horses, two gun teams, and 12 waggons; 49 native drivers were killed, wounded, or missing. The reprisals on these unarmed men was a feature of ferocity which amounted to wanton murder. We shall see later in this history how the unarmed Indian establishment of a Field Veterinary Hospital fared at the hands of the same men. On 28th October Methuen reached Zeerust.

Kekewich was able, towards the end of October, to slightly repay part of his debt by rushing a laager reported some distance north-east of Rustenburg. On 29th October, after a 25-mile night march, he accomplished his mission with very little loss, and was back at Rustenburg on 2nd November.

\* "Times History," Vol. v., p. 331.

† "Official History," Vol. iv., p. 298. This is a good record of Remount supply.

## NORTHERN TRANSVAAL.

SEPTEMBER, 1901—MAY, 1902.

When we last saw the Northern Transvaal it was in connection with Plumer's, and subsequently Grenfell's operations (pp. 165-167).

For several months Grenfell remained in the Northern Transvaal, surrounded by elusive enemies, to whom he gave no rest. Ably supported by Colenbrander, who knew the country and could play the enemy at his own game, Beyers and his Commandants had little rest. The enemy rarely took the initiative but had to be sought out; consequently the amount of marching done by this Force during the thirteen months it operated around Pietersburg was extraordinary, especially bearing in mind the inhospitable and unhealthy nature of the bush veldt. We can only glance at one or two of the most important operations, in order to give some notion of the amount of work demanded from animals in a district notoriously unhealthy, and which for some months in the year is fatal to all horses exposed to it.

The horse difficulty in the Northern Transvaal affected the enemy nearly as much as ourselves, and he found it necessary to conserve his Forces.

July and August were train-wrecking months, in which severe damage and loss of life was inflicted by the enemy. In September, Grenfell handed over command to Colenbrander, who, on 6th October, actually marched right across the north-western part of the country, through a most desolate and inhospitable area, until he struck the Mafeking-Buluwayo Railway. The privations encountered were considerable, 40 hours without water was not unknown; he returned through the same region, choosing a worse part of the country further north. He was not back at Warm Baths until 19th Nov., having just broken up a Commando after a 40-mile chase. Dawkins from the Free State had reached Nylstroom before he started, and while Colenbrander was away he worked down the Eastern side of the line effecting captures. On 23rd Nov., Colenbrander with Dawkins captured Badenhorst and his Commando after several days pursuit and fighting, and, but for the weather, would have secured Beyers who was chased 30 miles. On 13th Dec., the same combination went south-west and brought in more prisoners, but further operations in the bush veldt were now impossible owing to horse-sickness and malaria. Dawkins returned to the Free State on 27th Dec., and Colenbrander to Rustenburg. In his absence, Beyers attacked Pietersburg on 24th January, 1902, and got into the town, but was driven off after a hot fire. One object of this attack was to obtain horses from the Remount Depot and Veterinary hospital. C.V.S.R. Anderson, who was in charge of the hospital, was taken prisoner, but released after a few days. Throughout February Beyers was immobile through horse-sickness, so settled down in the almost inaccessible hills east of Pietersburg.

In March, 1902, he moved north, and attacked a post, Fort Edward, just south of Louis Trichard, and cut it off. Colenbrander was sent up from Krugersdorp to Pietersburg; on arrival he at once marched the 50 miles to Fort Edward, and inflicting severe loss on Beyers relieved the post. Beyers retired to his mountain fastness east of Pietersburg, and in April Colenbrander was strong enough to attempt to deal with him in this difficult position. The remaining period of the war consisted of operations, generally successful, in breaking up this Commando, but peace was proclaimed before Beyers was captured. The work done during the two months of April and May was most exacting and arduous. In the above operations the veterinary officers engaged were C. V. Surgeons W. C. Lowe (now Captain A.V.C.), and G. W. Lee (now Agricultural Dept., S. Africa), both of whom held Commissions as Captains in Kitchener's Fighting Scouts.

#### CAPE COLONY.

##### ATTACK ON CAPE TOWN.

OCTOBER TO DECEMBER, 1901.

It was in October that Maritz's scheme to attack Cape Town took definite shape; coming south by Clanwilliam in the first week of the month he held the garrison of Piquetberg confined to their position, and pushing on south crossed the great Berg River and made for Cape Town. On 11th Oct. he was at Hopefield, only *sixty miles* due north of Cape Town.\* French, who was on the spot, placed the three columns of Wyndham, Capper and Wormald (a new column) obliquely across his path, and Maritz, having made an attack on a squadron of the 16th Lancers, retired north under the pressure of the above columns. These followed him up between the sea and the mountains, and reached Clanwilliam, 80 miles north, on 24th Oct., by which time Maritz had safely retreated to one of his mountain fastnesses west of Van Rhyn's Dorp, 70 miles north of Clanwilliam. Wyndham then went on convoy duty to Calvinia, and Wormald and Capper continued to press north to the Olifant's River. But Maritz having now been joined by Theron took the opportunity of the coast being clear to make once more for Cape Town by the road out of which he had just been forced. On 31st Oct. he was again at Clanwilliam, where he captured and burned a convoy, and moved south. Wormald made a hurried return, doing 65 miles in seventeen hours over the sandy wastes of this low-lying country. Joined by Capper they continued their march south. Wyndham marched from Calvinia to Clanwilliam, 80 miles. On 3rd

Nov. Maritz was once more on the Great Berg River. To interpose between him and Cape Town Kavanagh was brought on 5th Nov. to Moorreesburg. Crabbe arrived in the vicinity on 10th Nov., and in the interval between those two dates Maritz might have reached the Capital. He, however, required horses, arms and ammunition for his rebel recruits, so in order to obtain these he sent Theron against the town of Piquetberg; the garrison drove him off after twenty-four hours fighting. On 9th Nov., Maritz, with his new lieutenant Theron, crossed the river making south, and on the 10th the former reached Darling. Matters were now most critical, but on this day Crabbe's column detained at Piquetberg Road Station, and marched south-west for Malmesbury 20 miles away. Here it again entrained, and on the following morning was south of Mamre. The latter place had already been touched by the patrols of Maritz; it is situated only *30 miles* from Cape Town. Crabbe's position enabled him to close the road to the capital to Maritz, who drew back, was followed north, and driven across the great Berg River on 14th. Kavanagh meanwhile having found Theron, chased him, and Crabbe leaving the further pursuit of Maritz to the columns of Capper and Wormald, now on the great Berg River from Clanwilliam, turned on Theron who was now actually behind him. Theron had his back to the sea, in front of him were Crabbe and Kavanagh, behind them the great Berg River, and at the mouth of that river lay a gun-boat. A gun-boat to deal with a Commando! Theron galloped past both columns, crossed the river 45 miles away from the gun-boat, and escaped north-east.

These operations led to a good deal of marching up and down and across the track lying between the sea and the mountains to the north of the Capital. The attempt on Cape Town produced a heavy draught on the horses, but was of more interest for its surpassing boldness and the immunity Commandos felt even when actually in the lion's jaws. This immunity was due among other causes to their greater mobility; they could always show a clean pair of heels. Our horses still carried too much weight.

After the retirement of Maritz and Theron, Crabbe marched to Lamberts Bay, Kavanagh to Clanwilliam, Wormald to Ceres, Capper remained at Piquetberg. Maritz disappeared until 28th Nov., when he unsuccessfully attacked a small post on the Brak River, 50 miles north-east of Calvinia, in quest of arms, ammunition and remounts. The place was invested for eight days and drew W. Doran and Callwell to its relief from Sutherland 100 miles away.

In consequence of the attempt to enter Cape Town, one of the most remarkable undertakings in block-house lines was now put in hand. It was no less than running a wire fence nearly half way across a sub-continent, *i.e.*, from Lamberts Bay to Victoria West, through practically a desert. The distance was 320 miles, and the work was undertaken from

\* Matters at this time were very serious, and marshal law was proclaimed in the Capital.

The "Times History" Vol. v., p. 541, estimates that at the beginning of November, 1901, there were not more than 1500 men in the field in Cape Colony belonging to the enemy, of whom six-sevenths were rebels. Yet, in order to deal with this handful there were at this time sixteen mobile columns employing 8000 horses, and many thousands of other troops in fixed positions.

both ends early in the month of December. Wormald went to Victoria Road to cover the working party at that end, Crabbe and Wyndham remained at the Lamberts Bay end. These two columns when protecting a convoy to Calvinia on 20th Dec. were sharply attacked, and again on 22nd and 23rd. Smuts, who was now in command of all the forces in Cape Colony, was present and directed the attack which was of the most determined character. The heaviest casualties occurred in the 16th Lancers, but the number of animals lost is unknown.

When Kritzingen re-crossed the Orange River in the middle of August, as narrated at p.169, he proceeded to the Zastron district where he remained resting for four months, surrounded by columns which were gyrating in the neighbourhood, though they never discovered him. During his absence from Cape Colony matters in the midland districts had not flourished, and Smuts urged him to return. The crossing of a river patrolled by columns was evidently a matter of ease to Kritzingen, who, selecting the historic Sand Drift used by De Wet, crossed with 100 men on 14th Dec. He was at once chased by the columns of B. Doran and Bentinck. Kritzingen's men had two or three horses apiece, and there ensued a long and a stern chase south in the direction of the block-housed line running from De Aar to Naauwpoort. On the 16th, at night, this was rushed after cutting the wires, but Kritzingen was wounded and captured together with other prisoners and 80 horses. The main body got through, and making for Hanover and Richmond, under the command of L. Wessels, got safely into the Camdeboo Mountains.

In November, while the stirring events already recorded were occurring close to Cape Town, a further attempt was made to deal with Fouché, in the almost inaccessible regions in the Drakensberg to which he fled when in difficulties. Scobell chased Fouché, Monro dealt with Myburg and Wessels, and their operations were successful in producing attrition, they captured 500 horses belonging to these Commandos, though the bodies remained at large. Myburgh was, however, too hard hit to take the field again. By the end of December the above columns, including a new Colonial Division of Cape Mounted Riflemen under Lukin, had driven these bands from pillar to post, though not across the Orange River.

#### WESTERN TRANSVAAL.

NOVEMBER, 1901, TO JANUARY, 1902.

During this period, the enemy did not offer any considerable opposition. De la Rey was not in evidence, and the operations mainly resolved themselves into minor drives and raids by Methuen and Kekewich in the Klerksdorp area, assisted by a column under Hickie. The quantity of stock captured during this time continued to furnish evidence of the resources of the enemy, and the

difficulties in clearing a country which had been traversed over and over again by British columns.

Both Methuen and Kekewich came from the north for these operations, where we last saw them between the Magaliesberg and Zeerust; on 18th November they were at Klerksdorp, having, of course, had to deal with opposition on the way. A few days before this time Hickie, when a short distance north of Klerksdorp, had suffered a serious loss in a reconnoitring squadron of Imperial Yeomanry, resulting in many casualties and the loss of over eighty horses. On 26th November, Methuen, Kekewich and Hickie moved out west from Klerksdorp, their transport was ambuscaded on the following day and seventy-seven horses lost. Methuen operating by night, continued his journey west, and then turning south-west was back in Klerksdorp, after several encounters; on 4th December he returned with prisoners, 14,000 head of stock, 200 draught animals and supplies.

On 11th December, after a week's rest, both Methuen and Kekewich again went west to the Makwasie Berg, a range of hills north-east of Wolmaranstad, which they searched and raided. After a considerable amount of successful marching and counter-marching they were back in Klerksdorp on 20th with prisoners, 36,000 head of stock, 480 draught animals, and immense supplies of grain. The grain brought in by all raiding columns was only a fraction of that discovered. The tons of food stuffs destroyed were incalculable.

On 28th December both columns again went west from Klerksdorp, once more in the direction of Wolmaranstad, Kekewich blocking the north, while Methuen harried the Makwasie Berg hills from the south. Methuen now hurried west after a Commando, which he subsequently missed, and reached Vryburg on 6th January; Kekewich, losing touch with him, went north, and after a good deal of marching arrived at Ventersdorp on 9th January with 7000 head of stock.

Other operations in the Western Transvaal in December were those prosecuted by Cunningham and Dalzell around the drifts on both sides of the Vaal in the vicinity of Lindeque, Rensburg's Drift, Witbanks, and other places.

On 8th January, Methuen again left Vryburg, and on 14th captured a small convoy in the vicinity of Harts River; another fell to him on 16th, in which his mounted forces rode fifty horses to death, and on 19th he entered Lichtenburg. On 21st he lost seventy-four horses out of a force of 200 sent to capture a supposed small party of the enemy which turned out to be a strong Commando. Methuen remained at Lichtenburg until 26th January when he started for Klerksdorp, where he arrived on 1st February. Kekewich, who had been busy raiding the district and protecting the blockhouse line in January, now on the completion of his section, again took more active measures. On 5th February he had a great success at *Gruisfontein*, a few miles east of Lichtenburg, where he surprised a laager, capturing 131 of the enemy and only losing 28

horses killed, though the range was but a matter of a few yards. On February 21st he returned to Klerkdrorp.

# *EASTERN TRANSVAAL.*

## *BRUCE-HAMILTON'S RAIDS.*

NOVEMBER, 1901, TO FEBRUARY, 1902.

Since last dealing with this theatre of war, important changes had taken place in the physical conditions, to which allusion must be made if the columns' movements are to be understood. The blockhouse lines had been introduced into the interior of the high veldt of the Eastern Transvaal, and had carved it up into areas which more readily lent themselves to treatment. The large protected area, extending from 40 miles east of Pretoria, north and south, to 30 miles east of Heidelberg, was still held by a line of Constabulary posts; Ermelo, in the middle of the high veldt, was connected with Standerton on the south by a blockhouse line, and on the north with Carolina, while the latter was linked up with the Delagoa line at Wonderfontein, a little west of Belfast. The Eastern Transvaal was thus cut in halves by a line of rifle fire over 100 miles in length, and in the middle of this desolate waste, in the very heart of the Eastern Transvaal, a supply depot was established at Ermelo, furnished by convoys which could now travel in safety by the blockhouse line from Standerton to Ermelo. This base in the enemy's country enormously facilitated the work of the columns, for, unwieldy transport could be left behind and columns thereby rendered more mobile, while the distance they had to fall back for food was relatively small. All this has a far greater bearing on the question of horse wastage than might at first sight appear. The shorter the time the troops are from their base the less the horse has to carry. The moment the weight on the back is reduced, the greater the available energy for military purposes. The blockhouse line never perhaps came up to strategical expectations. The enemy regarded it with contempt excepting when he had to cross it, but as a means of carrying war into the interior away from railways, with a minimum of animal labour and a maximum of safety for transport animals, it was superb. None of the work to be related in the present section would have been possible but for the existence of a supply depot on the spot. It only remains to be noticed that another blockhouse line ran from Volksrust in Natal, *via* Wakkerstroom and Piet Retief to the border of Swaziland, a distance of 60 miles, and thus cut off the bottom pocket of the South-Eastern Transvaal from the high veldt. This line also enabled the columns based on it to keep the Field.

The events immediately succeeding Bakenlaagte have already been referred to at p.173. By the middle of November twelve columns with 15,000 horses had been collected to avenge the disaster. Four of these were directly under Bruce Hamilton, eight others were to co-operate with him as required.

Hamilton disposed eight columns along the Wilge River line of Constabulary posts east of Pretoria-Heidelberg. Two hundred miles south-east were Rawlinson's Column at Volksrust, Colville's at Piet Retief, and between these two Plumer at Wakkerstroom. Botha was eighteen miles north of Bethel. The scheme was for Bruce Hamilton to drive the Eastern Transvaal with his column from west to east, and force the retreating burghers against the Swaziland border into the arms of the three columns above referred to as extending to Piet Retief.

The movement began on 16th November, and under cover of it the Constabulary posts were advanced fifteen miles further east, the line of columns advanced on Bethel, and finally on Ermelo, where Hamilton endeavoured to swing his long arms around the enemy, and make them either retire still further east or fight. The columns converged on Ermelo on 3rd December, and on the same day Botha's forces broke back between them, one body going north-west, the other south-west. Consequently, the drive, like so many of its predecessors, was barren. P. Viljoen was in command of the party which broke back north-west, and passed between the columns of Williams and Allenby. Botha guided the south-west party between the columns of Spens and Campbell, and on 3rd December was lying between Bethel and Ermelo, where he was raided at dawn on 4th by Hamilton, and heavy captures effected. Botha, with the bulk of his forces, went south-east, and found himself against Pulteney 750 strong, and Plumer 1000 strong, who had advanced north from Wakkerstroom, but nothing was effected.

On 9th December Hamilton again raided. A thirty-mile march at night brought him to a laager, which he captured; those who escaped were secured after a six-mile gallop; twenty miles back to camp completed a hard day's work. On the 12th the same troops made another successful night raid and covered fifty miles before their return to Ermelo. These are but a few of the night raids during this most productive campaign, and show the improvement which had resulted in the condition of the horses in consequence of food and care. The distances are given in the "Official History," and are, therefore, reliable.

On the 7th December Botha, undeterred by failure, was actually about twenty miles south of Ermelo; Spens was watching the blockhouse line, Standerton-Ermelo, but a short distance away, and on 18th December sent out a force of 200 M.I. to search a farm close to Botha's headquarters. The party was surrounded and lost 130 horses and a sixth of the men. The force under P. Viljoen which escaped north-west had been twice raided at dawn, on 10th and 13th December, by three columns with excellent results. He then put 200 men across the Constabulary line, who entered the "protected" area east of Pretoria and joined Prinsloo, where they remained until the end of the war. Mean-

\* Vol. iv., p. 375.

while, P. Viljoen himself with 300 more men entered the same area towards the end of January, 1902.

Bruce Hamilton continued to march east, and causing the north and south to be blocked, devoted the remainder of the month to night raids, which grew less successful as the enemy became more skilful in dealing with them. At the end of December Botha was still not more than twenty-five miles south-west of Ermelo, while Bruce Hamilton was against the Swazi border. An attempt was therefore made to get between Ermelo and Botha and drive him east towards Bruce Hamilton, Spens, Plumer and Pulteney doing the driving. The movement began on 1st January. On 2nd an advance guard of one of Plumer's Columns was captured; on 3rd December a serious reverse occurred also to one of his advanced patrols, in which the 5th Queensland Imperial Bushmen, 19th Co. I.Y., and two Companies of Regular M.I. were successfully ambushed, and lost heavily in men and all their horses. For three weeks longer Hamilton night-raided from Ermelo, and finally towards the end of January his columns repeated the drive on the Swazi frontier, but the results were small.

Botha, however, with 600 men left the Eastern Transvaal on 15th February for good, and, retiring south-east into the Vryheid district, never again appeared. The blockhouse line south was not tested, as he went round it through Swaziland.

#### NORTH-EAST TRANVAAL.

AUGUST, 1901, TO JANUARY, 1902.

A period of quiescence followed Blood's operations recorded at p. 167; most of the columns taking part in it had by now gone elsewhere, but Blood remained operating to the north of the Delagoa line. A combination of columns, Park, Campbell, and Kitchener, one being a flying column of Cavalry and M.I., made an attack on Muller near Elands River on 16th August, in which a party of the 19th Hussars were ambushed and lost all their horses. Then followed operations around Roos-Senekal and Dullstroom, which yielded little.

From September to December matters were very quiet. B. Viljoen and Muller were both present, but there was ample evidence to show the impossibility of ousting them from their mountain fastnesses; in consequence the people north of Lydenburg enjoyed immunity from British Columns and lived in comfort, for food was plentiful. This area, however, in December became the seat of the Transvaal Government, which broke through from the Eastern Transvaal when Bruce Hamilton began his operations in November. At the time there was only one British Column in this part of the country; it was situated at Lydenburg under Park, another was now sent from Belfast under Urmston to join with Park in tracking the fugitive Government. On 18th December this Column attacked Muller, who was escorting the party, and there

were many casualties, but the Government escaped. B. Viljoen, however, on returning from a visit to the Government was ambuscaded and captured on 25th January. A third column under J. Williams operated with the other two in February, and made a raid on Muller who was still covering the Government, and though many captures were made the governing body escaped and for safety proceeded further north.

With the above operations the military events for 1901 may be considered to have closed. The tedious details of movements we have narrated have been essential to a clear understanding of the question of wear and tear, which must now be taken up.

#### THE HORSE QUESTION IN 1901.

##### STATISTICAL.

Prior to our consideration of the operations of 1901, it was pointed out as an essential to a clear understanding of the wastage occurring in that year, that the war was waged by a force entirely mounted. While clearly pointing out that the excessive wear and tear was not materially due to any shortage of supply, as urged by the "Times History" (p. 147), opportunity was taken to insist that a powerful contributory cause to wastage—apart from want of condition of remounts—was the introduction into the country of 5800 new M.I., 17,600 new Yeomanry, and 6000 new Colonial contingents, to say nothing of the thousands of men raised locally, the exact numbers of whom are unknown. All these were more or less inexperienced in the care and management of horses, and none, excepting those locally raised, had a knowledge of their management on a campaign.

This must be borne in mind in considering the percentage of loss which had been anticipated by the War Office. We have seen, p. 142, that some years before the war occurred, it had been laid down that the wastage on a campaign would be five per cent per month.\* This was far too low, and in the face of the new data available† should have been revised. On the official basis of 5% per month, the number of remounts required monthly for a mounted force of 60,000 men would have been 3000. To what extent this was exceeded is shown in the following table‡ of remounts supplied by Major-General Truman during 1901, and does not include the horses brought to the country by Colonial Contingents and Regular re-inforcements.

\* R.C. Evidence of General Sir Mansfield Clarke, Vol. ii., p. 39.

† "The Loss of Horses in War," see footnote p. 142.

‡ "Court of Enquiry Remounts," Appendix B, p. 311.

NUMBER OF REMOUNT HORSES AND MULES  
SUPPLIED DURING 1901.

Total 115,458      22,692

---

Add Remounts on the Sea in  
Dec., 1900 (less loss), and  
not included in that year      5800      2950

---

121,258      25,642

---

Deduct Remounts on the Sea  
in Dec., 1901, not received  
31st Dec.      -      10,000      1000

---

Total Remounts from oversea  
received during 1901      -      111,258      24,642

---

The above total only refers to Remounts, and does not include the fresh horses coming into the country with re-inforcements as follows:—

Six Cavalry Regiments      3300 horses  
Colonial Contingents      6300

---

Total, after deducting loss at sea      9250

---

So that, speaking in round numbers, the total number of horses accompanying units, together with Remount horses and mules from oversea, during 1901, is as follows:—

120,500 horses      24,600 mules

Even these gigantic figures do not exhibit the full total. There were purchased in South Africa during 1901\* 92,699 horses and 16,245 mules.

\* R.C. Appendix 38a, p.260. It will be remembered, pp. 123, 132, that in 1899 it was reported that local supply in South Africa was unobtainable. In the two years and three months of the War which this history at present covers, no less than 146,918 horses and 16,245 mules were obtained as Remounts in South Africa!

Adding these to the imported animals we obtain

	Horses	Mules
Total number of new horses and mules obtained from all sources during 1901	213,200	40,845

Incredible as this total seems, it actually does not represent the total number of horses available, for it takes no notice of the tens of thousands of captured animals, very large numbers of which were used by the troops, if only for a day or two, but of which no record can ever be obtained.† A guess might be made as to the number so employed. For instance, at p.160, Major Mann reported 20% were available in the sweeping operations of Elliot's columns, and there is reason to think this estimate was lower than was subsequently obtained. In the absence, however, of reliable data we are compelled to pass over the thousands of horses "picked up" on the veldt, and confine ourselves to the figures above given.

The loss incurred by this immense number of animals, on the basis explained at p.141, is as follows for the year 1901:—

Horses **142,603**      Mules **14,433**

Again, it must be remembered that this was the dead loss only, and does not include the wastage arising from sickness and injury. Nor does it refer to any other animals than those paid for out of the public purse.

We cannot statistically compare the above loss with that occurring during 1900, for it has not been found possible to separate the three months of 1899 from the twelve of 1900 (see p.142). But for the sake of comparison we may place the tables side by side.

	Dead loss in 15 months, Oct., 1899—Dec., 1900.	Dead loss in 12 months, Jan.—Dec., 1901.
Horses	110,028	142,603
Mules	29,113	14,433

There is an increase of 32,500 horses lost during 1901 as compared with the previous fifteen months of the war, while a decrease in deaths of 14,700 mules occurred during 1901, as compared with the earlier period. This decrease may in part be due to the blockhouse lines; on the other hand it may be more apparent than real, for in round numbers only half the number of mules were supplied in 1901 as compared with the period Oct., 1899—Dec., 1900.

Perhaps a better way of visualising the loss is to calculate the *deaths* on a daily basis. For the

† Some idea of the numbers of captured stock may be gained from the fact that the columns which desolated the north-east of the Free State sent into Harrismith alone no less than 58,000 horses, nearly half of which were breeding stock. In these numbers everything was counted but foals. Harrismith was only one of several receiving centres, and the north-east of the Free State was a fraction, though the richest in horses, of the total area which had to be devastated in the Free State and Transvaal.

fifteen months, October, 1899 to December, 1900, these averaged :—

Horses	263 per diem.
Mules	63 " "

For the twelve months January—December, 1901, they averaged :—

Horses	387 per diem.
Mules	40 (nearly) " "

The monthly total wastage varied very little: at the end of the year 1900, it was reported as 25%.\* In April, 1900, it was still 25%.† On 1st March, 1902, the Q.M.G., in his evidence before the *C. of E. Rem.*, Q. 18, stated that the deaths and destructions in veterinary hospitals amounted to 1000 a week, and that this number did not include the mortality with columns [remount depots and farms]. We now know that these three sources produced an additional 1700 deaths a week.

The Q.M.G. added that there were approximately 20,000 horses on the sick list, but these numbers did not include the thousands recuperating on farms.‡

The dead loss of horses being 5.58% per month, and the general rate of wastage 25% per month, leaves 19.42% to represent the sick and debilitated. The sick, debilitated and weary therefore amounted to 41,400 horses a month, of which 20,000 or more went to hospital, and 21,000 or less to debility farms, or back to Remount Depots.

Briefly re-stating all the previous facts, and expressing them in round numbers, and in terms which readily appeal to the imagination, the mean loss in horses and mules every month during the year 1901 was as follows :—

		Monthly
Deaths and Destructions	Horses	11,600
	Mules	1200
Sick, debilitated and weary		41,400
Total Wastage		54,200

This is a truly appalling loss, the like of which had never previously occurred in an army subsequently victorious. We must now in general terms endeavour to trace its cause, and observe its subsequent effect upon the veterinary service. Before doing so, it will be convenient, at the risk of some little reiteration, to look at those losses on a large scale which have been recorded during the operations of the year under review; also those of certain individual units not previously specified in the text.

\* Col. 963, Cable 73.

† *C. of E. Rem. Appendix F*, p. 368.

‡ As a matter of fact the number of sick in hospital was frequently higher than the estimate made by the Q.M.G. In September and October, 1901, they stood in round numbers as follows :—

Week ending 25th Sept.,	remaining in Hospital,	26,500
" 2nd Oct.,	"	26,000
" 9th "	"	27,000
" 17th "	"	26,000
" 24th "	"	27,900

### CAUSES OF WASTAGE.

Examples of the excessive wear and tear of horses during the year 1901 are recorded in some of the Papers presented to Parliament. In Cd. 963, Cable 79, it is stated under date of 21st March, 1901, that the number of horses issued during the month of January to the troops operating in Cape Colony was no less than 12,000. The same Cable also informs us that the loss in horses of the various Columns in repelling in February the invasion of De Wet amounted to 5000.

French's operations in the Eastern Transvaal had used up 2,000 horses by the middle of March. We know that many of these died from horse sickness, and the Cable informs us that during the month of February alone, the loss in the Transvaal, mainly from this disease, exceeded 3000 horses!

In April, 1901, the officer in charge of Remounts, South Africa, informed the War Office that the wastage on the 55,000 mounted troops then in the Field equalled 25%. *C. of E. Rem.*, Appendix F, p. 368.

The Quartermaster-General, in his evidence before the *C. of E. Rem.*, gave an example of horse wastage in a regiment of Mounted Infantry. The original strength of the regiment was 492; in five months it received 556 fresh horses, so that the loss was over 100% in that short time. The strength of the regiment on the 19th September, 1901, was 391, and the following shows the effective state of the horses.

Fit, 13; fit in ten days, 30=43.

Unfit, 34; in hospital, 208 (sore backs and mange); destroyed, 106=348.

Out of 391 horses only 43 could be classed as fit, and this was the balance remaining of a total number of 1048 received during five months!

A witness before the *C. of E. Rem.*, Q. 6443, stated that on 12th May, 1901, the Metropolitan Mounted Rifles received 610 horses. They started on their march to Orange River, 80 miles away, and by the time they got there most of the men were dismounted. The witness did not tell the Court that these men, many of whom could not even put on a saddle or bridle, were mounted principally on half-broken, semi-wild horses, that had just been handled and backed, and but little more. Before the regiment completed its first march of 14 miles, the whole of their spare horses were loose, men by scores were marching on foot, while the track over which the regiment passed was littered with accoutrements of every description, including field glasses and rifles.

The previous witness, Q. 6445, said that two companies of Yeomanry, which were only performing outpost and convoy duty around De Aar, received 600 horses in two months. (The full strength of a Company of Yeomanry if every man was in the ranks is only 150. Full strength, however, is never realised in war, and it is unlikely that these two Companies possessed more than 100 men or so apiece).

In the *C. of E. Rem. Appendix F*, p. 312, a table of losses is quoted in a letter to the Inspector-General of Remounts showing the wastage in one month in General Elliot's Division which left Glen for Harrismith on 18th August, 1901, see p. 173. In that short time, out of a strength of 2936 horses no less than 969, or roughly one-third of the strength, had been lost.

The "Times History" grapples with the question of wastage during 1901 in its usual vigorous manner, and, having dealt with the monthly importation, adds:—

"Even this enormous supply was insufficient. Kitchener had failed to bestow the attention it deserved upon this important matter. Ground lost was never wholly regained. Quantities of animals were still thrown prematurely into the field, unfit and unacclimatised, quickly to succumb to the rigours of campaigning. The sickening waste of horseflesh which ensued was partly, of course, a corollary to the policy of tossing half-trained horsemen into mobile columns; but there was also much administrative blundering and much inexcusable neglect in the field. The remount camps and rest camps were not properly inspected, and it was not until November that Kitchener took effectual steps to remedy this defect. At the same time it is but fair to say that these camps—so constant and pressing were the demands for mounts—were never given a fair chance of becoming efficient and serviceable. In the field, even when the troops had become veterans, the consumption of horses was far too great. The regular troops were the best horsemasters and the Colonials the worst, but the standard throughout was not high. At one time, in imitation of the Boer practice, Kitchener tried the experiment of furnishing Columns with a quantity of spare horses. The result was only to encourage waste."

It is unlikely that those now living will ever know the real policy which lay at the root of the extravagant waste of horses, but so far as a close study of available material permits, it appears to have been based upon a misapprehension of the enemy's spirit of resistance. A misapprehension deeply rooted from the first days of the campaign and never, we believe, extinguished. It seems to have been considered that the terror produced by columns sweeping over the country, effecting captures, devastating property, laying waste the land, and removing families to concentration camps, would bring the enemy to his knees. With a nation less adamant, and less saturated with the religious fanaticism of being a chosen people, it is most likely that one, or at the outside two sweeping operations of this nature would have sufficed as an object lesson. Had such been the case the sacrifice of unconditioned horses would have been justified in bringing the war to a speedy termination. But the results of these first operations pointed the other way. Converting their land and houses into a wilderness only had the effect of stiffening resistance; removing their families to concentration camps, feeding them, caring for and educating their children, placed the Burgher on a far stronger war footing. Olive-branch proclamations were regarded as indications of weakness, and the bearers of them to the commandos were tried and remorselessly shot.

The enemy, through training and confidence, passed from the stage of defence to that of attack, and not only had already carried the war into a British Colony but maintained it there up to the last day of the campaign.

The loss of unfit horses early in 1901 would never have caused a second's consideration had the military policy adopted in January in the Eastern Transvaal been a success, for the end would have justified the means, and the means appeared at that time to be such as would attain the object aimed at. But a sacrifice which is justifiable as a temporary measure may be unjustifiable for permanent adoption, and we entirely agree with the *Times'* criticism—that the waste of horses was the result of employing unfit animals for operations demanding the highest physical condition, though we are unable to agree that this was in any way incurred through a lack in the purchasing of horses. See p. 148.

The *Times* does not allude to the other important factor involved in this question, i.e., the food supply. It is almost beyond belief that the daily ration scale consisted of only 10 lb. corn, and whatever else might be picked up from farms or by grazing! Of hay there was none excepting when near the line of rail, while grazing was variable and depended upon the season, the work in hand, and above all the column commander. Here lies the kernel of the whole question; horses cannot be got into condition without food. Even—as we venture to think—had it been possible to delay active hostilities for a few weeks so as to begin with animals fit for work, such fitness could only be maintained by a sufficient food supply, and from the first day of the campaign to the last this was not forthcoming.

The grazing frequently suffered at our own hands, for some columns destroyed the grass by burning, and left nothing but the blackened stones for those who had to follow them. But apart from this, it is a remarkable fact that horses should have been underfed at a time when a large army was engaged for a whole year laying waste an immense country, destroying thousands of tons of grain, and thousands of acres of crops. We never succeeded

\* This scale of grain ration is the same as that given to troop horses at home when leading a life of comparative idleness, and two pounds less than that given them when on peace manoeuvres.

Nowhere in the Remount Report on the War is there a word of protest against this semi-starvation scale of diet. See also p. 135.

The Report of the Royal Commission is also silent; it refers, p. 117, to horses and mules being "often on short rations," but it was evidently ignorant of the scale of grain rations laid down. It is impossible to conceive how such a highly technical enquiry could be carried out without expert knowledge; the interest of the horses should accordingly have been represented on the Commission, and evidence taken from veterinary officers who had served at the seat of war.

generally in learning to live on the country, or turning to our own advantage such supplies as it possessed. Of course, much was hidden away or the enemy could never have kept the field, while transport for discovered supplies was not always available. But making every allowance for these, we are not an army of thrift and providence, and it was always easier to destroy supplies by burning, or even turning them into a river,\* than to trouble to bring them in. This propensity for destruction was also stimulated by the military programme which enjoined it as part of a regrettable necessity.

Briefly, had we conditioned and fed our horses well, the miserable and shameful toll of waste during the year 1901 would never have occurred. It would then have been possible to deal seriously with horse wastage due to defective or bad management.

It appears to us that the months of March and April might have been devoted to getting horses into condition and putting flesh on them, though whether it was possible to stay military operations for this purpose is a question obviously outside this history. With two months, good feeding and steady work these animals would have been able to take the field with a monthly wastage which, at the outside, would not have exceeded 8%, as against the 25% actually occurring.† Two-thirds of the waste would have been controlled, and the proportion of remounts required correspondingly reduced. To replace the 8% monthly, 4800 remounts would always have required to be under training, a very large number, but by no means impossible when spread over the existing large depots. These horses would have needed 2500 men to train and look after them, but in this matter we were exceptionally well situated in South Africa, as the Kaffir is both fond of horses and can be made an excellent horseman. Thus, without drawing a single soldier from the fighting line, it would have been possible—given the above two months—to have “conditioned” all the horses required and sent them out fit for work. The training referred to is not, of course, the methods of the “High School,” but common-sense hardening of muscles and tendons, expansion of lungs, and adjustment of circulation, together with hardening and conditioning of backs, without which no horse untrained to the saddle is fit to carry a man.

\* The 60th Company of I. Y. was in April 1901, engaged in clearing operations in the South East District of the Orange Free State. A diary kept by one of its number reads:—“To Wepener—emptying large quantities of grain into the Caledon River. . . .” *Rhodesia and After*.—S. H. Gilbert, 1901.

† Into the same river a General was prepared to throw 22,000 sheep he could not drive further, unless satisfactory means could be found for taking them off his hands.

† This estimate would be higher for troops operating in notoriously unhealthy areas during the “horse sickness” season.

We have stated the outside rate of wastage, and the outside requirements, for it will not be forgotten that of the 8% normal wastage monthly, at least 4% would have been returned to the ranks, provided efficient means for collecting the horse *débris* of columns existed, and already at the beginning of 1901 the principles of such a scheme received official acknowledgment.

None of the earlier operations in the Transvaal and Orange Free State during 1901 were such as should not have been capable of being performed by horses in good condition, well fed and well cared for. It was not until towards the end of the year that long daily marches of forty, fifty, or even sixty miles were generally demanded. In the Cape operations, long and rapid marches were characteristic from the beginning, and the sacrifices in that Colony were on a totally different plane from those elsewhere. In the Cape the object was to hustle the roving bands out of the country, no matter at what cost. In the Transvaal and Free State it was not a question of driving them out of the country but hemming them in, and endeavouring to compel them to coalesce and fight; to drive them out of the country was the last thing desired. So that the conditions leading to the waste of horses in Cape Colony was not on all fours with those in the Free State and Transvaal.

We cannot leave the question of the employment of unfit horses for war in 1901, without reference to the official correspondence on the subject. All the following cables have been published in Parliamentary Paper Cd. 963, 1902.

The earliest is cable No. 74 from Lord Roberts (then at the War Office) to Lord Kitchener, in which he says:—

“The heavy wastage in horses is due, as we both know, to their being worked before they are fit. Would it be possible to commandeer, under Martial Law, in the districts of Cape Colony sufficient to enable the remounts to get a month's rest and exercise before being put in the ranks?”

In reply to this on 10th January, Lord Kitchener stated he was getting as many as possible in Cape Colony, and would do his best to give the remounts the rest required.

From the Secretary of State for War to Lord Kitchener, Cable 96, dated 21st November, 1901.

“Reports reach me from many quarters that the remount system is still unsatisfactory, and that unconditioned horses are being issued to columns and sent at once on long treks. Your telegram 20th September appeared to show there was then a proper margin. Cannot an officer of sufficient standing be appointed who would refuse to send remounts up country till fit? Surely it would be better to rest some columns for a time than to waste horses.”

To this Lord Kitchener replied on 25th November, 1901, Cable 97:—

"Your telegram 21st November. I am not thoroughly satisfied with result of remount work, though Birkbeck, who is in charge, is not wanting in energy. Could you send out Inspector General of Remounts to inspect, and let him bring with him some thoroughly practical officer or official to look after recovery of partly exhausted horses on hired farms.

With reference to your question, till the recent operations in Natal, which drew heavily on remounts, the best horses arriving had average of three weeks at ports, and weak or in any way unfit horses, longer. I hope I shall soon be able to return to this scale of rest. . . ."

The Secretary of State replied on the following day, Cable 98:—

"The question of resting horses seems to us of the first importance. We will certainly send officers to help you. But no change of hand will be effective unless you lay it down authoritatively that columns must rest till horses are in proper condition. We cannot continue indefinitely to send 10,000 to 12,000 remounts per month to be used up by column commanders in a few days."

To this cable no reply is published. A few days later, the 6th December, 1901, Lord Roberts, cabling from the War Office, No. 100, says:—

"Pray give the horses ample rest on landing, and impress on all Commanding Officers the necessity for animals being taken the greatest care of. The men should never be on the horses' backs when it is possible for them to be on foot."

On the following day, 7th December, the Secretary of State cabled as follows, No. 101:—

" . . . Lord Roberts is sending Lord Downe and Colonel Hotham to take charge of Remounts at the base in conjunction with Colonel Birkbeck, whose good work is fully appreciated. Several reports have recently reached me of horses from overseas being sent up country and sent on trek unshod, and consequently becoming unserviceable in two or three days. Cannot you issue an absolute prohibition of such practice? "

To this, Lord Kitchener replied on 8th December, 1901, Cable 102:—

"Your telegram of 7th December, I hope that Lord Downe and Colonel Hotham are being sent out only on a tour of inspection, and not in any way to interfere with work of the Remount Department under Birkbeck, with which I am quite satisfied. Horses are sent up from the coast ports to the large remount depots such as Mooi River, Elandsfontein, Queenstown, etc., where they are invariably shod before issue. . . ."

The Inspector-General of Remounts at the War Office now for the first time appears officially in connection with South African organisation, and on 9th December, 1901, sent the following cable (103) to Colonel Birkbeck:—

"Be prepared to keep 16,000 horses at base depots for one month. How are you off for 'corrals,' also for horse-keepers, native and European, respectively."

On 15th December, 1901, Cable 107, Lord Kitchener cabled to the Secretary of State for an additional establishment for three more remount depots, manned entirely by natives of India, and then adds:—

"A regular establishment is also considered advisable to ride these horses while at the remount depots, so that they

might get well conditioned and in regular work before issue to columns. I would suggest that for this purpose 500 Sowars of the native Cavalry, with saddlery complete, should be sent over here."

Beyond this date the cables are not published, but it is evident that throughout the year the question of unfit horses being issued to columns was agitating the minds at the War Office. Reading between the lines of the correspondence quoted, and the evidence taken before the Royal Commission, and Court of Enquiry on Remounts, it was apparently considered that an officer of the rank of Major-General was necessary at the base, in order to enforce the observance of a time limit.\* What a dual control of operations would have led to, does not require any deep powers of penetration. The question belonged to Lord Kitchener only. His cables show that he recognised that some period between landing and work was required, and when he mentions three weeks he doubtless gave the maximum which the military position permitted.

Three weeks represent about one third of the time these horses required before joining columns, not for rest, as the cables indicate, but for work. No machinery existed for conditioning riding horses. Captain Bessie, A.V.D., with the remount department had, as we have seen, introduced into the depot at Bloemfontein a means of exercising masses of animals, and materially conditioning those required for draught purposes, but the conditioning of saddle horses cannot be effected entirely by this means, though it may largely be helped. A riding horse requires to have a weight on his back, *he cannot be conditioned without it*, for part of his training consists in conditioning the muscles of the back and loins, and any horse not so conditioned is liable to fail in the back within a day or two. The symptoms are those of partial paralysis of the hind quarters, and the number of remounts abandoned or destroyed from this cause was astonishing.

The question of conditioning horses entirely centres around the military situation. We have seen from our history that it grew progressively worse, and that the number of mounted troops had to be increased, so that supposing hostilities had been partly suspended during March and April to admit of the conditioning of animals then standing at a strength of 156,000, the difficulties would have again arisen when the force went up to 244,000, as it did in September. Nevertheless, the opinion of a layman in these matters, if he can be permitted to hold an opinion on such a highly technical question, is that 156,000 well-conditioned and well-fed animals would not have necessitated the great

\* This is what the Government said on the matter in the House of Commons:—

"The Government are sending out horses so as to get in advance of requirements, and give the animals a month's rest before going into the field. A general officer had been lately sent out to take command of this department alone, and to see that no horse was sent up country that was not thoroughly fit for the purpose."—*Times* Report, 1st February, 1902.

increase later in the year, for every month the enemy was losing men,\* and had no further resources, excepting in the Cape operations, for recruiting purposes. We hold the opinion that it was our relative immobility which encouraged the resistance of the enemy, and that consequently a smaller body of fit and well-fed horses would have accomplished more than the vast hordes of unfit, unacclimatised and underfed animals. It may be said than an allowance of fourteen pounds of grain daily (a minimum for large horses) would have been impossible from a supply point of view. If so, we had better give up making war with mounted forces. But as a fact it would not have been so; 75,000 horses on 10lb. corn would have allowed 50,000 horses a daily ration of 15lb. Can anyone doubt, after the account which has been given of the work they were called upon to perform, which of these bodies would have secured the best tactical results?

Neither the regimental officers nor veterinary service are to blame for the low ration scale. We started the campaign badly in the matter of food (p.14), and we maintained throughout the war a position which was indefensible from the horse-master's point of view. We actually allowed to the horses in this campaign 2lb. less of grain than is given to animals during peace manœuvres! A soldier's horse, as well as the soldier himself, requires to be well fed in war, and any cheeseparing policy at such a time is suicidal.†

Throughout the whole length of the campaign it is difficult to call to mind a single instance in which we caught up, the retreating enemy. Bothaville (p.109) may be cited as an example, or the attack on De Wet by Plumer when the former was crossing the Kimberley line during his attempted invasion of Cape Colony (p.155). But speaking generally the enemy were safe from capture, which no one knew better than they. It ought not to have been so, further, it would not have been the case had the horses been highly fed. If the fuel is not available the machinery stops.

\* See Appendix, "Official History,"

† The Campaign in the Crimea is a classical example which one would have thought ought never to have been forgotten. Six thousand pack horses were at Varna awaiting embarkation for the Crimea, they were subsequently sent to Constantinople to form a reserve depot for animals. The Commissariat Department, "no doubt remembering their instructions to 'cut things fine,'" kept these animals on half rations. The Commissary-General stated before the Royal Commission that "the animals were not worth their keep." When this reserve arrived in the Crimea, "thanks to the half-ration régime at Constantinople, 'they lost no time in dying.'"

After 14th November no hay was issued, and only 2½ lb. of barley per horse. "Enormous quantities of forage were available a few days' sail distant." A hydraulic press put up at Constantinople to press hay for Balaclava, was erected 15 miles away from the hay.

See "Army Administration in the Crimea," Captain R. D. Barbor, A.S.C., *Journal of the Royal United Service Institution*, July, 1913.

### THE CONTROL OF WASTAGE.

There are a sufficient number of causes of horse wastage on service without increasing them by semi-starvation. Losses would have been experienced had a good corn ration been given, but such losses would have been due to causes incidental to war—hard work and exposure—and they would have been only one-third of those actually experienced. The moral effect upon those charged with the care of partly starved horses is largely responsible for much of the neglect and indifference in management exhibited by the regular troops—artillery excepted. When officers and men were called upon to do the impossible with horses, a spirit of indifference and want of care was soon accentuated, fostered by the fact that fresh animals awaited them. That the large number of available animals had this demoralizing effect is neither excuse nor condonation, but the fact was patent to everyone. The rank and file are at all times difficult to interest in the welfare of their animals (artillery excepted), and it becomes absolutely non-existent when a fresh horse is received every few days. We are not here, however, dealing with the want of horse-mastership, that will be considered as a general question later, but only attempting to show how far-reaching was the effect of the deplorable policy of underfeeding animals in the field.

Another question connected with the series of cables printed at p.188 must now be looked at. Cable 96 of 21st Nov. from the Secretary of State, says that the *Remount System* appears unsatisfactory, and proposes a remedy. In the reply Cable, No. 97, Lord Kitchener expresses himself as not thoroughly satisfied with the remount work, and proposes a remedy, *i.e.*, the Inspector-General of Remounts to inspect, and a thoroughly practical officer or official to look after the debility cases on the various farms. We are not at present concerned with the latter question, which deals with the recuperation of war-worn horses. The primary matter in Cable 96 refers to unconditioned horses being sent into the Field as soon as they were landed, and to meet this it is asked that the Inspector-General of Remounts at the War Office should come out and inspect. Cable 101 would seem to show that the Inspector-General of Remounts could not be spared, and a Major-General of Cavalry and a Colonel of Artillery were accordingly to be sent out "to take charge of remounts at the base." This was not the scheme proposed in Cable 97; accordingly Cable 102 is sent to the War Office; this is difficult to reconcile with Cable 97 so far as the general remount work is concerned. It makes clear, however, that the officers being sent from home were not to take charge of Remounts at the base, but were only to be regarded as on a tour of inspection and were not to interfere.

Now, these Cables have a far deeper interest for the Veterinary Service than lies on their surface. Lord Kitchener's Cable, No. 97, of 25th Nov., 1901,

makes a distinct statement of dissatisfaction with the result of the remount work only, and the reply to this by War Office Cable 98, of 26th Nov., promises the remedies he has asked for. On 1st Dec., 1901, the Chief of the Staff in South Africa published an Order—to be quoted in full presently—appointing Colonel Long Inspector of Veterinary Hospitals, Remount Depots, Farms and Mobile Columns.

The effect of this Order, so far as the Veterinary Service was concerned, will be considered later; what we are anxious to do here is to trace the connection between Colonel Long's appointment and Cables 97 and 98 of the 25th and 26th November. Here we are assisted by a private letter from Colonel Birkbeck to the Remount Department, War Office, which has been published in Appendix F to the Court of Enquiry on Army Remounts.

The letter is dated 27th November, 1901: . . .

"—\* has detailed—\* to make a searching inspection of all our depots and farms and of the veterinary hospitals, and to report to him exhaustively on the whole subject. Personally, I am very glad, because I think—is a good chap and knows a horse, and I do not think he will find anything wrong."

This letter shows that on the 27th November Lord Kitchener had decided to cause the inspection work of remount depots and farms to be carried out by an officer of his own selection. Curiously enough the above letter intimated that not only are remount depôts and farms to be inspected, *but also Veterinary Hospitals*. There is nothing in the published telegrams which passed between Lord Kitchener and the War Office to suggest that he was dissatisfied with the way the veterinary hospitals in the country were being conducted. His complaint is against remounts, though subsequently even this appears to have been withdrawn. We are now confronted with the remarkable fact that a purely technical institution of another branch of the service, possessing its own departmental head, and with which no fault has been found, is to be included within the scope of an inspection duty connected with the organisation of remount management, and carried out by a layman. We shall look at the qualifications of the inspector so appointed, but in the first instance we must endeavour to ascertain how it was that the veterinary service became included in the pilloried remount service.

Earlier in this history, p. 134, we drew attention to a Parliamentary Paper bearing the number Cd. 963, published in 1902. This paper contains several distinct matters:—

- (1) A report by Lieut.-Colonel Birkbeck, dated June, 1900, dealing with the organisation of the Remount Department on active service, and the supply and issue of animals in the field.

- (2) A report from the principal Veterinary Officer, Pretoria, dated July, 1900, dealing with the veterinary aspect of the campaign up to date.

- (3) Questions in regard to Remounts, addressed by the Quartermaster-General to officers employed in remount operations in South Africa, for the period ending December, 1900. Replies to the above questions are furnished by Lieut.-Col. Birkbeck, dated 22nd December, 1900; the General Officer Commanding the Line of Communication in Natal, and Colonel C. H. Bridge, C.B., C.M.G. (Director of Transport in South Africa from October, 1899 to January, 1900).

- (4) Statistical tables dealing with Remounts.

- (5) Telegrams and extracts from telegrams despatched and received between June 1899 and January 22nd, 1902, in reference to the purchase of Remounts.

The report which we have numbered (1) above, was written during the month following Lord Roberts' capture of Pretoria. We have already at pp. 114, 134, drawn attention to it in connection with the question which it raised of veterinary hospitals; we have now to look at it in connection with an adverse criticism it contains on the veterinary service, together with a suggested remedy.\* This is what Colonel Birkbeck says in his report of June, 1900, on the relationship of the Veterinary and Remount Services:—

"*Relation of Veterinary and Remount Departments.* There should, I think, be one head to control the general organisation of both Veterinary and Remount Departments, I mean as regards the location of the veterinary field hospital, and the disposal of animals returned from the front.

In this connection the two services are so closely allied that it is difficult to draw the line of demarcation between their spheres of action. Thus, veterinary field hospitals, sick horse farms, and remount depôts, are better controlled by one and the same head, who should be responsible that useless animals are not kept and fed at the advanced depôts.

There is a natural reluctance to destroy the wrecks of fine animals which it is difficult for the professional veterinary enthusiast to overcome, and such animals, though useless for the present campaign, are apt to be kept in veterinary field hospitals eating rations which are more valuable the further they are brought from the coast.

By all means let the technical work and distribution of veterinary stores be carried out by the Principal Veterinary Officer, *but it requires a Staff Officer of wider training—if I may be excused for saying so—than a Departmental Officer is likely to possess, to direct the general policy of the veterinary operations.*"†

We now know that as early as June, 1900, the Assist. Inspector of Remounts in South Africa was satisfied that the Remount and Veterinary Services should be under and controlled by the same head. We acquit Lieut.-Colonel Birkbeck of any attempt

\* It is necessary to explain that when 1 and 2 were written the campaign was regarded as over, and reports from heads of departments were accordingly called for. Parliamentary Paper 963 is merely a mixture of various questions affecting horses, occurring at widely different periods of the war.

† The italics are ours.

\* Blank in the original.

in this report to take the veterinary crown off Colonel Matthews and place it on his own head, for the reason that when this report was written the war was considered at an end. Nevertheless, as a graduate of the Staff College,\* he would naturally consider that he was not devoid of the "wider training" that the Departmental Officer was never "likely to possess," and qualified by his then limited experience of this service in the Field, to lay down regulations for its guidance and undertake its management. He got others to agree with him: this necessitates an examination of Paper 3, as classified above.

The questions regarding Remounts (No. 3 above) are addressed by the Quartermaster-General of the Army to officers employed in South Africa, and are fourteen in number. In none of these is the Veterinary Service alluded to: the Quartermaster-General regarded the Remount and Veterinary Services as quite distinct,† and the fourteen practical questions to which replies are desired, do not in any way touch upon veterinary matters. Colonel Birkbeck, who again appears, evidently thought otherwise, and in reply to the question "Can the organisation of remount work ‡ on the lines of communication be

improved, and, if so, in what way?" replies as follows:—

"I answer this question on the assumption that the organisation referred to is that laid down in the Yellow Book,\* which has not been strictly followed in this campaign. The Yellow Book directs that there shall be a Director of Transport who shall control both the Remount and Veterinary Services. In South Africa he controls neither, rightly, I think, but I do believe that the efficiency of the Veterinary Department would be increased and its general policy controlled by the Assist. Adjutant-General of Remounts † indicated below." (A diagram not here reproduced).

"The Assist. Adjutant-General of Remounts to be constantly up and down the lines, in touch through his Deputy Assist. Adjutant-Generals, and personally with headquarters, base, sections of the lines of communication and Generals of districts, detailed columns. (The latter part of this sentence is not very clear, some word may have been left out). He can thus anticipate requirements and mass his animals where they are likely to be required, the Assist. Adjutant of Remounts should also control the general policy of Veterinary Department, making it fit in with Remount Depots." ‡

The above reply is not without a suspicion of humour. He personally objects to his department being under the Director of Transport, but urges twice, what he has never been asked, that the Veterinary Department shall be under Remounts, and its policy controlled and made to fit in with that of the Remount Department,

Another reply to the Quartermaster-General's questions must be reproduced, it is furnished by Colonel Bridge, late Director of Transport in South Africa. He selects the same question as Colonel Birkbeck for introducing his views on the Veterinary Service, which as above pointed out was not the subject of inquiry.

Colonel Bridge says, p. 28:—

"The sick-horse depôts should be under the control of the head of the Remount Department."

The Quartermaster-General asked no questions about sick-horse depôts. Had he so done, it would have given the General Officer Commanding Lines of Communication, Natal, an opportunity of expressing his views on the Transport-Remount control of the Veterinary Service, to which he was entirely opposed. He regarded these services as distinct, and that each should be under its own departmental head, who should be responsible to the General of Communications.

In these extracts from the replies to the Quartermaster General's questions we miss the views of the late Director of Supplies. Not being connected with Remount work, the questions were not sent to him, but nevertheless we are not without his opinion. In his examination before the Royal Commission he presented a memorandum || on many subjects, some of which were absolutely alien to his department, and among the latter were

\* The Staff College gives a higher professional education. After its theoretical course of two years or so, an infantry officer by going for two months to a battery of Artillery learns about horses, guns, ammunition, and interior economy: two months with Cavalry teaches him what other men spend a life-time in acquiring, and so on. It is, therefore, easy to understand that looking on at veterinary work for six months would, *a priori*, render a staff college graduate a veterinary expert.

† Evidence of Quartermaster-General before the Royal Commission on the War. Opening statement.

Q. 2358. As regards the Army Veterinary Department, which was placed under the Quartermaster-General in November, 1901, the best evidence will be given by the late Director-General Veterinary-Colonel Duck.

Q. 2359. Will that be conveniently taken without the Remount Department? A. It is entirely distinct; the administration of the Department is entirely distinct.

Q. 2360. But both deal with horses? A. He provides the medical attendance for horses, but he would provide for the medical attendance for the Remount Department in the same way as he would for a mounted unit.

Attention is drawn to question 2360. The Chairman could not understand that the department dealing with the remount side of the horse question was not also the same as that dealing with the treatment of horses when sick. Such reasoning should logically place the Recruiting and Medical services of the army under one head. Curiously enough, much later in the enquiry, Lord Esher is surprised to learn that the Intelligence Division of the War Office should be expected to furnish information as to the capabilities of foreign countries to supply horses, and in Q. 12,982 exclaims: Why the Intelligence Department? A. Because it is in close touch with all the Embassies, and it is the Department which procures information on every point connected with foreign countries. Q. 12,983. They are not experts? A. They are not experts.

Did Lord Esher consider the Remount Department experts in veterinary matters? The answer is furnished by the recommendations of a Committee on War Office re-organisation, of which he was President, which placed the Veterinary Service under the Remount Department.

‡ The italics are ours.

\* See this History, p. 114.

† The italics are ours.

‡ Idem.

|| See R. C. Appendix 35, p. 345.

his own views on Veterinary Hospitals and who should control them. The interest he has taken in the organisation of the Veterinary Service is, to say the least, remarkable.\*

It would probably strike him as astonishing if an official memorandum had been prepared by an officer of the Veterinary Service for technical evidence before a Royal Commission, in which he ventured to criticise the organisation of the Supply Service in war, and lay down authoritatively the system by which in future it was to be conducted. Yet a parallel course has been pursued by the late Director of Supplies.

This is what he says in the memorandum referred to above:—

"SICK HORSE DEPOTS."

"Sick horse depots should be directly under the remount administration. . . ."

The remaining paragraphs of his remarks will be found at p. 135.† Incidentally it may be mentioned that in the above memorandum he proposes that the duties of the Supply and Transport Services shall embrace not only supplies and transport, but disembarkation, railways, including construction, Remounts and Veterinary Service, the latter being under the former.

Among the witnesses examined by the Royal Commission was the late Director of the Remount Department in India, Colonel Deane. He made a tour of the seat of war in the capacity of a Staff Officer of Yeomanry and was brought much in contact with the Remount operations and its Assistant Inspector. His evidence is very interesting as being that of an expert trained in a country where war is a chronic condition. The only part of it we intend to deal with here, bears on the subject at present under examination.

In Q. 13,071 he says "Then again, a point which struck me, if I may refer to it, was that the English War Tables show that the arrangements of Remount officers in the field are in charge of the Director of Transport who has also control of the Veterinary Service. As a matter of fact, he was in charge of neither one nor the other, and very rightly, because it was impossible for him to control both in addition to the vast transport service. The control should have been placed in the hands of the Inspector or Director of the Remount Department, and I think he should not have been under the rank of a Major-General."

This witness, with the authority attached to his late position, was another means of drawing the attention of the Royal Commission to the benefits to be derived by subordinating veterinary work to remount control in the manner, as he himself expresses it,‡ "so well suggested by Colonel Birkbeck."||

It would certainly appear from the evidence quoted that no opportunity was missed for securing

a subordinate position being assigned to the Veterinary Service.

We are now in a position to understand the appointment of Colonel Long as Inspector of Veterinary Hospitals. Lord Kitchener was committed by his cable 97, to take steps to remedy his dissatisfaction with the Remount Department, but it is evident from cable 102 that he did not approve of the appointment made by the War Office, which would in effect have tied his hands. The next best step was to make an appointment of his own, and he selected Colonel Long. There can be little doubt that the views of Colonel Birkbeck, so clearly expressed in his reports of June and December, 1900, were placed before Lord Kitchener.\* Representations of the difficulty in extracting cases from hospital, † of the retention under treatment of horses not considered by the Inspector of Remounts as offering a prospect of recovery, ‡ and of the reported inability of the veterinary department to understand staff requirements(p.191), would appear to have influenced him in making a combatant officer an Inspector of Veterinary Hospitals. The Remount Service thereby dragged down with it the only branch which had hitherto enabled it to keep afloat, or at any time to gain credit for it.||

It may be urged by some that this appointment was rendered necessary by the inability of the Veterinary Service to manage its own affairs. This history shows that it could not manage its affairs without hospitals or personnel, neither of which existed until borrowed from India. The majority of its officers had then to learn the work as they were civilians without military training; there were no administrative officers for purely hospital service, and consequently no one specially told off to teach them.\*\* They next had to train the subordinate personnel in hospital duties, and in spite of these four extraordinary sources of weakness no reproach, in the correspondence we have examined, has been urged against veterinary hospitals, other than that they did not destroy a sufficient number of horses to keep the forage bill down, or send out unfit animals for duty. Nevertheless, a real reproach existed. They were congested to an extent which no one could have anticipated, owing to the enormous amount of inefficiency which existed. To this were added the inability to obtain either the necessary amount of labour for looking after the animals, or a large enough staff of skilled subordinates to carry out the treatment. For none of these defects could the Veterinary Service be held responsible.

\* See Colonel Birkbeck's letter dated 27th November, 1901, reproduced at p. 191, written some few days before the order on the subject was published.

† This History.

‡ R. C. Appendix F, p. 587.

|| It will further be observed that the language employed by Colonel Deane is almost identical with that used by Colonel Birkbeck two and a half years previously.

The following is the Order which was published :

“ Commander-in-Chief's Office,  
South Africa,  
December 1st, 1901.

Colonel Long has been appointed Inspector of Veterinary Hospitals, Remount Depots and Farms. All Departments will give every assistance, and carry out Colonel Long's requirements and suggestions with the least possible delay.

Colonel Long will also, when possible, inspect Columns with regard to the state of horses and their treatment when out on trek, and make any suggestions for the improvement of the horse management and the care given to horses on the trek.

He will see that the local Veterinary Officers inspect all Columns carefully on arrival at a station and before leaving, to ensure that no horses remain with Columns who require veterinary treatment, or go out on trek when not in a fit state to bear the fatigues of the march.

IAN HAMILTON (Lieut.-General),  
Chief of Staff.

The effect of this Order upon the veterinary service was stupefying; hitherto with all their difficulties they had been able to show results, and to lead the Remount Department on right lines where given the opportunity. That the hospitals were capable of improvement this History abundantly testifies, though great advances had been made since 1900. The difficulties which existed in 1901 were intensified by congestion, the result of a sick rate averaging 20,000 or more animals a month,\* and want of proper accommodation and cover for the sick which could not be supplied. An improvement in the structural requirements of hospitals was urgent; proper enclosures each containing only a limited number of animals, ample water supply, ample manging, some cover for the worst cases, protection against cold for the debilitated. None of these points had been neglected in the way of representation, but the branch of the service charged with these duties was busy with block-house lines, accommodation for sick men and stores, and had, over and over again with the best intentions, failed to comply with demands which it was known were reasonable, but for which neither labour nor material could be diverted. Every representation made by the Principal Veterinary Officer to the Commanding Officer Royal Engineers in South Africa was received with sympathetic consideration, but there was the old cry “the war may end any day,” and in the meantime what was considered more urgent work had a prior claim. Officers in charge of hospitals cried aloud to the P.V.O. for their requirements, and probably often thought their complaints fell on deaf ears. It was not so, but the P.V.O. was not armed with the same powers subsequently possessed by Colonel Long, who was authorised to order in Lord Kitchener's name everything he considered necessary. The pendulum now took a violent swing in the other direction: quite a feverish activity prevailed in carrying out improvements, and in building stabling. Money was poured out like water. A new hospital, costing thousands, could be obtained with-

\* Towards the end of the year as many as 28,000.

out hesitation, and not always with due discrimination as to the requirements of the place, or the oscillating centres of the campaign. The work was carried out under conditions approaching panic, which is always extravagant.

The structural improvements following on his inspections were considerable; the same could have been effected by anyone armed with Lord Kitchener's direct authority. As to the veterinary work, Colonel Long was far too well informed to interfere,\* while a veterinary officer on his staff always accompanied him.† He devoted his energies and authority mainly to the betterment of accommodation, and improving the conditions under which the veterinary work was carried out. For these improvements, though they came late, we can scarcely be too grateful. But, as above stated, the work carried out by him in connection with the improvement of veterinary hospitals could have been better carried out by an officer of the Veterinary Service armed with the same authority, whose technical knowledge would have rendered him a more completely valuable instrument, and we venture to think a less expensive one.

It must not be inferred from Colonel Long's appointment that the inspection of hospitals was not carried out by the Senior Veterinary Officers on the line and by the P.V.O. The administrative officers were few in number: 1 to Natal, 1 to the Free State, 1 to Cape Colony; the Transvaal fell to the P.V.O. With such a microscopic staff for a sub-Continent it was impossible, with the many other duties, to do more than make periodical visits to the forty-two hospitals which existed over the country at the end of 1901. There should have been three Veterinary Inspectors of hospitals, one each in the Cape, Free State, and Transvaal, charged with no other duties than passing from hospital to hospital, and by the closest supervision and initiative extracting the best results. Such appointments, with power to order necessary repairs and accommodation, would have been of immense value, such as no lay Inspector of Veterinary Hospitals could ever hope to attain, even though, as in the case under consideration, he was a man of exceptional knowledge of horse management.

Without detracting from the six months good work which Colonel Long was able to accomplish in connection with the building of hospitals, it must be remembered he was armed with powers such as no other man wielded during the war. The influence of his appointment on the Remount Service is another story; and does not fall to us to narrate, even if the facts were fully known. His service in connection with the inspection of columns was of the greatest benefit. It is true he could see but

\* No doubt at his visits he pressed for or ordered the destruction of horses. It is known, for instance, that he ordered 350 scabies cases to be destroyed at Standerton on 17th June, 1902, but this was after the war.

† It is clear from the pages of this History that the small numbers of the A.V.D. in South Africa did not admit of this loss to its executive.

few of the scores in existence all over the vast theatre of war, but as a protective measure the appointment was of the greatest importance. For the work to have borne the best possible fruit, there should have been half a dozen instead of one Inspector of Columns.

#### ARMY ORDERS ISSUED DURING 1901 TO CONTROL ANIMAL WASTAGE.

The animal wastage occurring during 1901 did not escape the attention of the Commander-in-Chief. On 24th January, the following Army Order was published on the question, and incidentally it serves to indicate the first appearance of a definite order for Columns to collect their own animal wastage. The officer referred to in the Order was always the veterinary officer when one was present. The scheme was the germ of official recognition that something must be done in the matter of collecting the animal *débris* of war.

#### CARE OF HORSES.

It has been brought to the notice of the General Commanding-in-Chief that sufficient attention is not paid by Column Commanders to the care and well-being of the animals upon which the mobility of their columns so much depends.

The following rules are published for guidance :—

(1) Horses should not be saddled up unnecessarily early and kept standing.

(2) The mounted troops of the main body will walk and lead their horses for a considerable distance each day. Every opportunity must be taken by individuals of dismounting whenever halted even for a few minutes.

(3) Halts should, if possible, be made at previously arranged times and for fixed periods at spots where the grass is good.

If considerations of safety admit, the girths should be loosened, saddles shifted, and bits removed to allow the animals to graze. The equine stomach is small, and requires constant filling.

(4) Opportunities should be given for watering horses after the sun is well up, and again about mid-day and before sundown.

(5) Officers commanding Columns will arrange for an Officer, with a sufficient number of kafirs on ponies, to collect and drive along with the baggage column all weakly and sore-backed horses which are unfit for duty.

This party will collect and bring along all derelict horses, British or Boer, fit to travel and likely again to become serviceable—those unfit or utterly useless must be destroyed.

The waste of horse-flesh will thus be diminished, and spare horses accumulated by columns.

On reaching the railway these animals should be handed over to the Remount Department.

(6) Weakly horses should not be sent with flanking parties.

On 22nd February, 1901, an Order was published that no sales of cast or debilitated animals were to take place.

On 22nd February, 1901, there were further orders regarding animals being abandoned, and it was prescribed that horses and mules with Columns, if unfit for work, should be sent to the nearest military post for transfer to a Depot or Veterinary

Hospital, as opportunity occurs. If too far from a military post to carry out the above Order the animals were to be destroyed.

Apparently no good results followed these Orders, for on 2nd April, 1901, another was published on the subject, and the wear and tear of Columns was directed to be reported weekly. Even the salvage of animals indicated in the previous Order would not appear to have been carried out, and in consequence the "Rules" laid down on 24th January (see above) were republished as an addendum to the following Order :—

#### CARE OF HORSES.

The G.O. Commanding-in-Chief fully recognises that, under certain conditions where some important advantage can be gained by rapid and sustained movement, the sacrifice of horses may become a military necessity.

On the other hand, there are many occasions where columns are not in absolute touch with the enemy, in which by more care and attention to the length of marches, watering, feeding, grazing, marching the men dismounted, and off-saddling, the present waste of horses and mules might be avoided, or at least greatly reduced.

In a number of cases at present, the wastage is little justified by the results obtained, and does not reflect credit on Column Commanders.

The G.O. Commanding-in-Chief, therefore, trusts that Officers Commanding will use every endeavour to keep their horses in good condition, thereby reducing to a minimum the heavy strain now experienced by the Remount Department.

Officers Commanding mobile columns will send in every Saturday to Army Headquarters a weekly telegraphic state specifying :—(a) The number of horses in possession at the commencement of the week ; (b) the number of horses killed, died, and destroyed during the week ; (c) the number returned to Remount Sick Lines ; (d) the number unaccounted for ; (e) the number received from Remount Department or other sources ; (f) the number remaining in possession at the end of the week. Similar information should be furnished regarding mules.\*

Officers Commanding Columns should remember that horses abandoned on the march are generally picked up and used by the enemy. Every effort should, therefore, be made, and natives should be employed, to bring in such horses, and where it is impossible to do this they should be destroyed.

Commanding Officers should give every assistance to Local Captain Macdonald and his agents, who are employed to collect stray Government horses, cattle, etc.

The collection of the stray animals by columns, referred to in the last paragraph of the order, draws attention to the formation of a Live Stock Recovery Department which was created on 7th January, 1901, and has been already referred to at p. 120.

Another measure for the preservation of animal life was embodied in an Order first published 25th April, 1900, and republished on 7th July, 1901, in which the burning of the veldt was prohibited, either by the carelessness of the troops or intentionally by farmers. It is astonishing considering that the whole force of horses, mules

\* On 24th January, 1901, an Order had been published directing a weekly report to be furnished of the casualties among transport mules and oxen.

and oxen in South Africa were officially dependant on the veldt for their hay ration, that wanton destruction of large grazing areas was caused by some column-commanders firing the veldt, and leaving the area to be subsequently traversed by columns a blackened wilderness. When orders were issued to destroy crops some commanders fired the grass in an excess of zeal, a futile proceeding as far as the enemy were concerned, and a disastrous one for our own animals. It is incomprehensible how men could have been found to scuttle their own boat thoughtlessly, for though horses and mules had a small corn ration, the oxen were entirely dependent upon what they could obtain by grazing.

The overloading of transport waggons, drawn attention to in the Army Orders of 1900, had steadily grown until the transport early in 1901 was out of all proportion to the force it accompanied, see Fig. 1. The following Army Order dated 29th July, 1901, reveals the situation:—

"It has come to the notice of the General Commanding-in-Chief that in many instances the allowance of baggage authorised for mobile forces is greatly exceeded, and that transport allowed for supplies is used to carry miscellaneous collections of unauthorised articles. Captured transport, instead of being handed over on the force reaching the line of communication, has in some cases been retained with mobile columns and used to convey such articles as cooking ranges, furniture, and even pianos and harmoniums.

"It appears that it is necessary to remind Commanders of Columns that the essential factor of a mobile force is mobility, and that nothing should be carried beyond what is requisite to feed men and animals, and to maintain fighting efficiency.

"If Columns are habitually impeded by unnecessary transport they cannot act effectively, and Lord Kitchener directs officers commanding mobile forces to ascertain personally that all superfluous equipment, baggage, stores, and vehicles are in future dispensed with."

As the practice continued in spite of the Order, it was later on directed that the above should be read to the troops not less than once a fortnight.

In connection with this matter, and bearing on the question of horsemastership, a witness before the Court of Enquiry Rem., stated, from personal observations, that he had known oats left behind in order that baggage might be carried.

Q. 3819. Is it within your knowledge that these horses were properly fed at the front? A. I am quite aware that it was impossible to feed them at times, and impossible always to give them the attention that they would require, but still, if anything went wrong with a column they would throw off the oats first and carry on the other baggage.

Q. 3820. Is that hearsay? A. No, I have seen it myself; if a waggon broke down they would unload the sacks of oats in order to load up probably another waggon containing furniture. I do not want to make any sort of charge, but from the Remount point of view that was very exasperating.

The Commander-in-Chief was equally concerned for the care of his transport oxen, as may be seen from the Army Order of 5th January, 1901, referred to at p. 144.

On 28th November, a Memorandum was issued by the Adjutant-General, in which the Commander-in-Chief directed that only horses which were really fit for hard work were to accompany Columns, and that for the unfit a temporary base was to be formed on the line. The horses so left behind were not to be employed on any duty. It was further directed that remount horses were not to accompany Columns within seven days of their receipt from the Remount Department; until then they were to remain at the Column's base.

The number of horses left at this base was to be reported, and Column Commanders had to notify the Remount Department, after each trek, of the number of animals they had been compelled to return to Remount Depots and Veterinary Hospitals.

The same order directed the formation of a mobile Veterinary Hospital in each column. It was specially stated that cases of sore back were to be at once handed in to this hospital, and that if no spare animals were available the men must walk.

The war had been in progress two years before mobile hospitals received official approval. It is true they existed in several places, but their employment depended upon the Column Commander. They were now, for the first time, directed to form part of each Column, but the order came too late. With the appointment of Colonel Long—a few days later than the above Order—veterinary assistance was largely withdrawn from columns and placed on the line, so there was no one to take charge of the mobile hospitals. This policy was the opposite of that pursued by the P.V.O.; the disadvantage of a dual control was not long in manifesting itself.

#### VETERINARY HOSPITALS, 1901.

During the last month of 1900 it was decided by the authorities that *one* thoroughly equipped Veterinary Hospital should be erected, equipment and personnel being withdrawn from other hospitals and sources, to complete what was intended should prove a model establishment. The place selected for its creation was Elandfontein, close to Johannesburg, and within three miles of the largest Remount Depot in the country. The site was at an altitude of some 5,800 feet, and was practically safe from horse-sickness. Here was developed under successive administrations, but mainly under that of Major Pringle,\* a hospital with stabling for 500 sick, general accommodation for over 2,000 horses, together with a good subordinate staff, and equipment for dealing with matters on a basis not previously permitted.

The beginning of the year 1901, saw this hospital in full work, and it is fortunate that during the remainder of the war the Head-quarter Staff of the Army, and others, had an opportunity of seeing the organisation the Veterinary Service could put into their hospitals when given a free hand and assistance.

\* Now Major-General Pringle, C.B., D.S.O.

From January to December, 1901, the total number of admissions to this hospital at Johannesburg was 24,606. An analysis of these cases is valuable as showing the class of disease met with on active service:—

	Admitted.	Cured.
Debility	6785	2506
Mange	5049	3549
Lameness	4994	3560
Sore Backs	2747	1592
Wounds	1938	460
Glanders (clinical cases only)	238	—
Quitters	236	195
Various	2619	2732
	24,606	14,594

Out of 24,606 cases 14,594 were cured and returned to duty; 6540 were destroyed from various causes, and 2142 died. The balance of 1330 remained under treatment. The weekly average for the year would accordingly be:—

Admissions	473
Discharged to duty	280
Deaths and Destructions	167

In round numbers it may be said that nearly 60% of the admissions were cured and returned to duty, sufficient evidence, if any were required, of the value of a hospital. The deaths and destructions were 35·2%.

It is interesting to know what work was being accomplished by some of the other hospitals in South Africa during 1901.

	Months	Cured	Died and Destroyed.
At Middelburg <sup>o</sup> Transvaal	in 7	56·5%	24%
Kimberley	8	63	24
Stormberg	12	65·8	25·8
De Aar	6	74	15·25
Orange River	6	26	20

The latter was a typically bad hospital. It will be observed the death rate was no higher than in the other hospitals, but the cases were not got out to duty.

The good results obtained by hospitals were brought to the notice of the War Office later in the year, who were asked to authorise the formation in South Africa of a Field Veterinary Hospital to contain 2,500 cases, with the following staff:—3 Veterinary Officers, 4 Non-Commissioned Officers, 5 Shoeing Smiths, 4 Privates, 25 Veterinary Assistants, 5 Conductors in charge of natives, and 520 Natives, on the basis of one to every five horses. Extra duty-pay was allowed to the Non-Commissioned Officers. The scheme was a good one, its only weak point being the small proportion of Non-Commissioned Officers, who should have

\* I have to thank Major Cochrane, A.V.C. for this information.

been at least ten in number, for supervision is the keynote to success. It is to be regretted that approval was only given for *one* hospital on the above scale, and this at a time when the War Office knew that there were always twenty to twenty-eight thousand fresh cases of sickness occurring monthly, among the horses in South Africa.

At the beginning of 1901 there were 38 Field Veterinary Hospitals dotted all over the country, and varying in strength from 300 patients to 3000. Towards the end of the year there were fifty such hospitals. The work these did was of unequal value owing to local difficulties, want of organisation and personnel, and the inability of some of those in charge—many of whom were civilians—to adapt themselves to military methods and requirements without experience and training. It is for this and other reasons we have stated that an Inspector of Veterinary Hospitals for each Colony should have been created, with no other duty than passing from hospital to hospital, organising, assisting, directing, and showing the right way to obtain the best results. Had such a system existed and the inspecting officer been empowered to order what was absolutely necessary, there would not have been any occasion for the appointment of Colonel Long.

An effort was made to have hospitals arranged on a general plan, the details of which naturally varied with local conditions. Such a scheme was intended as suggestive, and showed the officers in charge what was expected from them. All, however, were not equally apt in making the best of local conditions, while, on the contrary, others showed initiative which reflected itself in their general good arrangements. One of the greatest drawbacks was the absence of authority on the part of the Civil Veterinary Surgeons in charge; they could give an order, but to enforce it, or to deal with breaches of discipline necessitated invoking outside aid—a weakening of the general structure which nothing could correct but military status and rank.

The local facilities for hospital organisation differed at every place. Some stations lent themselves readily to the purpose, others were equally refractory. Water was the great difficulty, and without an ample supply no thoroughly good work could be done. Military considerations frequently restricted the available site, and some Commandants had an idea that a hospital for animals was associated with something so excessively unpleasant, that the most unfavourable and out-of-the-way position was allotted it.\* An instance of this occurred at Belfast in November, 1900, p. 151, where

\* The notion that a veterinary hospital was an offensive institution, to be kept as much as possible out of sight, had not died down after the war. When the site for the present cantonments of Pretoria was laid out, it was proposed that the veterinary hospital should be placed far away on a flank, adjoining the ground used for the disposal of the cantonment excreta! It is obvious that a hospital to be of any use must be centrally and conveniently situated to the troops for which it is intended, and on uncontaminated ground.

the hospital, having been pushed almost beyond the entrenchments, found itself during the night attack on that place exposed to the fire of defender and attacker; but for the fog it would have been captured by the enemy, who passed close to it. At Stormberg, a piece of ground quite unfit to hold its 500 sick was all that was considered available, owing to the difficulties of providing it with defence. The position was hopelessly restricted, and a better one was only given on the understanding that the hospital would dig and man its own trenches for defence.

If suitable sites and water supply were difficulties, they were nothing compared to those experienced in getting anything erected in the form of shelter or protection. The local engineer officers were anxious to help, but said their men were engaged on block-house work, and that all constructive material sent by rail was for block-house purposes only. Over and over again did the P.V.O. in Pretoria endeavour to arrange with the Commanding Royal Engineer for a start to be made by the construction of shelters, especially at those places known to be affected with horse-sickness. A type of building had, in the first instance, to be "got out" on paper and approved, in which the primary consideration was to be cheapness. Month after month building operations were deferred from one cause or another, congested railways, supplies, movement of troops, block-house lines, etc. All of these were quite true, but the delay was mainly, no doubt, due to the belief that the war might "end any day."\* In the meantime the Veterinary Service in charge of hospitals had been making bricks without straw for over a year, and felt that their claims to some consideration in the matter of accommodation for their sick were being overlooked. It came as a positive relief to many, after the first shock of the Long appointment (p. 194), to know that they only had to ask in order to receive. The more they asked for, and the more pressing the construction was represented to be, the better the Inspector of Hospitals seemed pleased. He harassed the Engineers under threats of pains and penalties, and galvanized life into the construction of stabling, manging and enclosures. Especially was stabling necessary for those hospitals situated on the table land of the Eastern Transvaal. Here, and down to the border of Natal, the winter was

very cold, and the only chance of recuperating the debility cases was to screen them from the bitter wind. But anywhere on the table of South Africa the winter is cold and the wind trying. De Aar or Stormberg in Cape Colony, might in this respect rival Standerton in the Transvaal.

Speaking in general terms, the all important structural details for hospitals were water-troughing, manging, and good enclosures. The system of trying to feed without mangers is shockingly wasteful of forage, every pound of which having been sent from 5000 to 7000 miles across the sea, was then thrown in the dirt or sand, and picked out or trodden underfoot as may be. The absence of mangers led as much as anything else to condition not being regained. What equitable distribution of food could occur when it was thrown down on the ground in a line, pawed up by anxious feeders, or blown away by the wind? If the horses had had food in them they would have felt the cold less, and in fact wind screens would have sufficed in the majority of instances, with a certain amount of stabling for the worst cases. Nothing can take the place of mangers; they are the first consideration as far as horses are concerned in a standing camp. Few people outside the mounted branches appear to realise their paramount importance.

The activities of the mobile hospitals, of which the first took the field in Natal early in the war (pp. 85, 86), were sufficiently good to induce the authorities to approve a partial extension of the system. Such hospitals can never be more than a connecting link between the sick in the field and the Field Hospitals on the Line of Communications. If they become congested they are useless; the keynote of their effective management is evacuation. By April the personnel, stores and equipment for a few mobile hospitals had been fixed, but above all the transport, without which it could not move. Further, its staff was mounted. Men who have been trudging along with troops all day are not fresh enough for work when the bivouac is reached. It was during General Elliot's sweeping movements in the Eastern Free State (p. 160) that a mobile hospital was given a thoroughly good and extended test, and proved, under the organising capacity of Major Mann, the S.V.O., how useful it could be made.

Those columns without a regular mobile hospital had, as we have seen from the Army Order of 24th January (p. 195), been instructed to make better provision for the care of sick animals on the march. In the operations conducted by General French in January in the Eastern Transvaal this make-shift system was brought into general operation and proved most useful. Unfortunately, no transport at this time was allowed for the work, which meant that no equipment was carried other than in the regimental waggons. This was not only insufficient but impracticable; the sick and derelicts when collected had to be kept together, and herded somewhere for the night, and this meant that equipment for dealing with them was necessary. Those veterinary officers

\* Sir Fleetwood Wilson, who went out to South Africa as Financial Adviser to Lord Kitchener, says that whatever he accomplished was done as the result of "coaxing," in spite of the exceptional advantages he possessed in knowing personally those with whom he had to deal, and having been associated with soldiers all his life. He is, of course, representing his position as a civilian, but nevertheless he was a member of the Headquarter Staff of the Army. See R. C. Evid.: Vol. i., p. 253.

It is not everyone who possesses the striking personality and persuasive powers of Sir Fleetwood Wilson, so that a good case may fail for want of the needful "coaxing" powers; in the military hierarchy, not only are the difficulties of adopting this line considerable, but it would be subversive of discipline.

who were possessed of initiative "found on the veldt" the transport and waggons required, and literally made their own arrangements. Later on, as previously mentioned, regular field establishments and proper transport were allowed to some columns, but by no means all.

It is nothing less than extraordinary the grudging methods followed in tackling the sick-horse question even fifteen months after war began. Money was poured out like water by other branches, but any makeshift was considered sufficient for the needs of the veterinary service. This applied not only to the mobile hospitals but everything else connected with the department in the Field. We believe there was a genuine desire on the part of the military authorities, not only to diminish the waste of horses, but also, as far as was practically possible, to diminish some of the cruelty which must ever be practised in war, but it is remarkable that the efforts of the veterinary service in this connection met with so little substantial support. The transport problem is always a difficulty: as early as April, 1900 (p.144), attention had been directed to it. In the first half of 1901 it had become serious, and columns were carrying about with them "miscellaneous collections of unauthorised articles." \* The Commander-in-Chief found it necessary to remind his Column Commanders "that the essential factor of a mobile force is mobility, and that nothing should be carried beyond what is requisite to feed men and animals, and to maintain fighting efficiency. † From this Order it is evident that a fraction of the transport employed for the carriage of unauthorised articles, might well have been devoted to conveying appliances and means for rendering effective first aid in the field, and in collecting and taking the sick along. The importance of their duty would have been emphasised had these earlier mobile detachments received proper official recognition, and a scale of staff and stores been laid down. It came months later, and, like most other things, too late. On 28th November, 1901, it was directed "In order to reduce the present very heavy wastage in horses," that among other measures Mobile Veterinary Hospitals should be formed in *each* Column, page 196 . . . . On the 1st December Colonel Long was in charge, and on 19th, under his instructions, orders were issued by the P.V.O. that a number of veterinary officers were to be withdrawn from Columns in order to strengthen the personnel of the Field Hospitals on the Lines of Communication. Thus, mobile hospitals having been approved for all Columns, after two years wastage of horses through their absence, were once more relegated to the background. Those already existing did not disappear, but became altered in nature; each large Field Hospital furnished a mobile section, but it was only mobile in the sense that it could be moved from pillar to post on the Lines of Communication. What was required was an organisation with the troops, call it what you may, for dealing with the

exhausted, injured and sick, under central and organised management, and responsible for bringing such cases along until fit to be returned to their unit or handed into hospital on the line being reached.

The great difficulty in all hospitals, whether stationary or mobile, was to obtain efficient and permanent personnel. Almost every man in the hospitals existing in the country was borrowed, with the exception of those belonging to the ten Indian Field Veterinary Hospitals, and the one sanctioned by the War Office at Elandsfontein in September. Some of the men employed were deliberately hiding away from their regiments, and were not recovered for months. If he was a useful man, above all a skilful dresser, it was not to be wondered at that no active steps were taken by the hospital authorities to find out where the man's regiment actually was. But, of course, such a system is indefensible.

The year 1901 had seen considerable changes in the personnel of the hospitals raised in the country during the campaign. India had sent a large number of trained dressers, who were distributed amongst them. Civil shoeing smiths, drawing £180 a year and rations, existed by scores, and were also distributed, and useful men among the Dutch population were brought in from time to time as conductors. \*

The personnel so acquired gradually took the place of the soldiers who had been borrowed, or otherwise obtained; even then senior non-commissioned officers were required, and these had to be retained throughout the war, though in theory they should have been serving with their regiments. Nevertheless, the whole fabric of the hospitals was unsubstantial, from the Civil Veterinary Surgeons whose time was expiring and who wished to return home by the next ship, to the Kaffirs who deserted after pay day and were seen no more. There should be no such thing as a "scratch" institution with an Army: if it is necessary it should be recognised, organised, and placed on a proper basis.

Much has to be done by the personality of the head of affairs in removing official opposition to the introduction of new ideas. † There are many men and many minds on the Staff of an Army, but if there is one subject on which most of the minds are agreed, it is that of affording as little recognition as possible to veterinary requirements, pushing them into the background, and trusting to time to adjust difficulties. It is the old story of the medical department, with the exception that public opinion has scarcely been aroused in the matter of the horses, in spite of the size of the remount bill. That, after all, is a lower plane than the real one on which we think this question should finally be judged; we owe a moral obligation to animals which cannot be evaded.

\* Army Order I., 29th July, 1901, p.126.

† Idem.

\* This was a proceeding not without danger, for these men necessarily became possessed of information.

† See Footnote, p.198.

The more organisation and permanence introduced into these Field Hospitals the greater the correspondence which arose with other departments, especially that dealing with finance. The Indians were paid by a specially appointed official who dealt with all Indian natives, both with the Remount and Veterinary Services. All others were paid by the Chief Paymaster, and the very large sums of money needed necessitated the officer so employed being made what is technically known as an "accountant," entailing a considerable amount of financial responsibility and elaborate accounts.

The opposition of the Remount Department to Veterinary autonomy died very hard; it never became wholly extinguished, and the young officers of this service were, as usual, the most aggressive. At Orange River a remount officer expressed his intention to inspect the hospital and demanded returns of sickness. At Aliwal North the bold measure of clearing the sick out of the hospital and monopolising the services of the Civil Veterinary Surgeon for purchasing duties was adopted. At Mafeking the cases cured at the hospital were refused by the Remounts, as no information could be given of the units to which the sick originally belonged! Doubtless there were many similar though unrecorded cases of interference. These small matters indicated the feeling still held by remounts towards the veterinary service, though it is right to record there were many exceptions, especially among the senior officers, some of whom were not slow to recognise that undivided responsibility is the first step towards sound work.

One important step taken in Jan., 1901, was a form of return rendered weekly by all hospitals showing exactly how they stood in the matter of patients, the numbers admitted and discharged, the diseases they were suffering from, the staff employed, and the condition of the equipment and stores. The return was so arranged as to reduce clerical labour to a minimum; in a few minutes a document was prepared which enabled the administration hundreds of miles away to feel the pulse of every hospital throughout the country, and see matters as they were actually occurring. Postal services during war are irregular, so that weekly telegraphic states were rendered on a code form previously arranged, which not only reduced the strain on the telegraph department, but took but a few minutes to prepare.

Before closing this notice of the hospitals in 1901, it is due to those members of the profession who assisted the army in a civil capacity to record the ability shown by some of them in hospital management, and in mentioning the names of C.V. Surgeons J. I. Smith, J. Buck and J. M. Parker (the latter a Canadian graduate who died in office) as men showing conspicuous ability and power of organisation, it does not detract from the merits of others whose good work was unfortunately less known.

#### PROTECTION HORSES, 1901.

In the account for 1899-1900 we drew attention at p.132 to the fact that two distinct classes of local horse came into our possession during the war, one being captures, the other for protection. It was pointed out that in the rush of affairs no system for dealing with these existed, nor indeed had the matter even been considered.

Protection-horses were those brought in from districts in Cape Colony to prevent them falling into the hands of the enemy, and though tens of thousands were similarly brought in from districts in the Transvaal and Orange Free State, the use of the word protection could not be applied to these, as they were swept up in countries with which we were at war. To this stock the term "captures" is applied. They were brought in in pursuance of an order that no living animal was to be left behind.\*

It was in December, 1900, that the comparative peace and tranquility which had for so many months reigned in Cape Colony was suddenly disturbed by the attempted invasion of De Wet, and the actual invasion by Hertzog and Kritzinger. The military authorities at once realised the danger of leaving on the various farms of the invaded districts such a potential source of warfare to the enemy as the horses represented, and Commandants of districts, together with Magistrates, were directed under Martial Law to collect and hold these animals at centres where they would be safe from impressment by the enemy. It was further directed that from these horses all available remounts should be selected and, of course, paid for. We have seen that there was no system for dealing with these thousands of animals, which consisted of horses of all classes, including breeding stock and foals. Doubtless it was at first thought that the emergency would soon pass, and the animals could then be returned to their owners. This idea was rudely dispelled by the second attempt of De Wet to enter the Colony two months later, and it was then recognised how imperfect had been the first collection of material, for, from the animals left on the various farms he had no difficulty, with the aid of Hertzog, in making good his immense loss in horses. Stringent orders were consequently issued, and thousands more brought in. Still no system existed for dealing with them.

Lord Kitchener in April, 1901, issued orders that Columns operating in the Cape were in future to be remounted from local supply only; † the animals so obtained were drawn from protection stock on payment, and on requisition from the inhabitants. As we have already seen, p. 152, footnote, 15,000 were obtained in this way in January, and by the following July 75,000 animals had been obtained from the same sources, in a country previously reported to be unable to furnish a horse supply. In spite of

this heavy drain there were at this time thousands of horses on protection farms, some useful, many useless for military purposes, generally as the result of impoverished condition due to starvation. Efforts were made to train and render fit for the use of Columns some of the vast numbers remaining, and in this respect the Remount Depot at Kimberley was particularly successful, and on a smaller scale the Depots at Stellenbosch and De Aar.\*

It was at Harrismith, as we have seen at p. 132, that the first steps in dealing with this class of stock had been taken in 1900. Similar operations were carried on through 1901, the whole of the new Yeomanry with Rundle being mounted more than once, and various Columns in the vicinity replenished. Breeding stock formed about one-half of the captures brought into Harrismith by the various Columns whose movements have already been narrated, and as far as possible an attempt had been made to retain this for the future development of the country. It represented the cream of the Free State studs, and no one had any previous notion of what this consisted.†

Colonel Matthews, in a note written at Standerton in May, 1901, describes his inspection of the 5000 head of stock resulting from one of Elliot's drives. "I spent a most interesting two-and-a-half hours watching these 5000 animals, brood mares and stock, from yearlings to six years old. I had now spent four years in South Africa, and although perhaps I ought to have known, yet I had no conception such beautiful brood mares existed in the country." In a further note he remarked on the facility with which the Australian and New Zealand soldiers converted the brood mares—unbroken even to the halter, and many as old as fourteen years—into saddle horses in the course of three weeks. This, however, could only dispose of a very limited number, and, as opportunity offered, both from Harrismith and the Transvaal, breeding stock, estimated at from ten to fifteen thousand, was sent to Natal. The bulk of this material went to Mooi River; when seen shortly afterwards, overcrowding, starvation and neglect had done their work, and cannot be better described than in the language of one who witnessed it: "It broke my heart to see these magnificent mares, many nearly, some quite thoroughbred, dying slowly from starvation and a variety of diseases." Colonel Matthews says in a note written after inspecting some of this stock at Mooi River: "I found fourteen mares had aborted in one paddock; one or two carcasses were lying around in a state of decomposition, and the burial pits, where seven horses awaited interment, were only sixty yards from the main horse enclosure." If the above state of affairs could exist in a large horse station like Mooi River, under the nose of the Remount Department, with horses now the property of the Crown, it can be imagined what occurred at the dozen or more places in Cape Colony where

protection horses were confined. Evidence was given before the Royal Commission on the War by Lord Lovatt who, in discussing the waste of public money in the purchase of horses, described one of the Cape protection farms. He says:—

"For example, 6000 horses, mares and foals were near a place called Burghersdorp, and there was no apparent reason that they should not all have been used for His Majesty's Forces. They were good mares and young horses; there were few absolutely fit to ride at once without training, as the mares in South Africa, although broken to harness, were never broken to riding. The mares were all kept in this place, and apparently no one seemed particularly interested in the matter, and the remounts had them in charge; they were left to run over two or three small farms, and they gradually pined away and wasted for lack of food. No one was allowed to take what they wanted of those, and at the end of the war these 6000 horses had diminished to about 700 or so.

Q. 20,752. Were these captured horses? A. They were cleared off farms; I have seen perhaps 1500 or 1200 sent to this farm in one drove.

Q. 20,753. And they were chiefly mares which would not have been used for Cavalry? A. Yes, mares; but there was no reason why they should not be used; they only required to be broken and to get a little condition on, and they would have done as well as horses.

Q. 20,752. During that time were you not in want of horses? A. Yes, and I took them when I passed there, but I was not allowed to take them. I asked leave on one occasion, and I was refused.

Whether the Remount Department should have been permitted to burden themselves with the care of these animals is another question. In our opinion, absolutely not, for their hands were already too full. As far back as 5th December, 1900, the subject of the disposal of the captured stock was already exercising the mind of the Assistant Inspector of Remounts, for in a letter to the War Office he says.†

"That mare and foal business is arriving at rather alarming proportions. We are practically clearing the Free State and Transvaal of breeding stock, and transferring it to the Colony and Natal into loyal hands at nominal prices. Of course in time it must all get back to the grazing countries."

This shows how ignorant we were of the horse resources of the country, for the work of clearance had not yet begun and already the number of stock to be provided for was alarming. No provision, however, was made, not even six months later, by which time tens of thousands of captured and protected stock had to be legislated for. It was not, in fact, until October, 1901, that any definite regulations were drawn up for the care of the protection horses in the Cape. The regulations created a "Protection" branch of the Remount Service, but by that time the majority of the horses were dead. Pending the creation of this branch the animals fell to the care of local commandants, who knew nothing of horses, and whose sole anxiety was to prevent their recapture. The wretched creatures were herded at night inside infantry entrenchments, and each day marched solemnly to grazing grounds a short distance away, bare of everything

\* At one time De Aar employed fifty roughriders.

† See foot note, p. 185.

\* Q. 20,751, Vol. ii., Evidence, p 479.

† C. of E. Rem. Evid. Appendix F, p. 366.

but the bones of those which had died. No rations were allowed them. How could they be when our own horses in the field were on a semi-starvation diet? When a remount depot was adjacent they came under its care, as at Burghersdorp quoted above, and in active centres like Stellenbosch the suitable were selected for breaking and trained. Of course, this class of material had no right inside a remount depot, which it only congests. As an example, in July, 1901, there were 100 two year olds being hand-fed in the Remount Depot at Stellenbosch, with no possible prospect of any return for the rations given them, and the hay which was denied our own horses in the field.\*

When protection horses were brought in the owner's natural desire was to have his stock purchased outright, and in some cases this was actually done under misapprehension. See C. of E. Rem. Evid. Q. 6515.† Rightly, the authorities negatived any such wholesale purchases excepting for suitable animals, and it was also made clear to the owners that no compensation would be given for loss, and that the animals must take their chance. The regulations, introduced, as we have said, in October, at least gave something definite to act upon; we cannot enter into them. In the coast districts, considered to be safe from the enemy, the horses were registered and remained with their owners; elsewhere they were concentrated on farms. In October the registered horses remaining with their owners amounted to 18,000, the protected horses on farms stood at 22,700, all that was left of certainly double the number, probably more, of the previous January.

The formation of a Protection Department did not stop the mortality. The horses in many cases were past recovery; in some districts the entire herds looked like dying, and the residue was given to farmers to look after. The mortality was due not only to starvation, but disease introduced and disseminated by the unavoidably indiscriminate mixing of sick and well, the young and old; but more especially from starvation, the result of overcrowded grazing grounds. The latter had to be confined to areas under military occupation, and were already well grazed by the transport, or to areas in the neighbourhood of the line of rail or other military posts. Another cause of mortality was due to change of grazing; animals from the midlands were sent south where the herbage differed, or those from the east were sent to the west. Any sudden change from their old to a new grazing district was a source of loss, not only owing to the difference in herbage but from poisonous plants. Animals reared on pasture containing the latter learn from experience to avoid them; the new comer falls a victim. Strangles was rife among these horses; glanders frequent;

\* These two year old horses were being allowed 12lb. hay daily, thrown down on the ground.

† The witness, a Remount Officer, says:—

"At one time there was an order given by mistake to buy every horse, foal, mare and everything. I bought those and, of course, they had to be sent to a farm."

parasitic disease of the intestinal wall abounded and hastened dissolution under the hardships to which they were exposed.

The arrangements made in October at a cost of about £3000 a month were good, but came nine months too late to be of any real benefit. In October, 1901, 22,700 horses were taken over, and some small numbers were added month by month throughout the war. The numbers so added are unknown, but when the war closed there were a little over 12,000 survivors on farms. The deaths between October, 1901 and May, 1902, amounted to 10,500, say 46%. If 46% died in six months when arrangements costing £3000 a month existed for their care, we can imagine what the mortality was during the nine months prior to October, 1901, when no arrangements existed. It is probably not too much to say, that between January, 1901 and May, 1902, not less than 80% of the Protection stock died, or was destroyed, from disease or starvation.

The account we have given of protection farms differs materially from that briefly recorded in the "Times History" of the War, Vol. vi., p. 444, in which the following appears;—

"An interesting development of the duties of the Remount Department was the protecting of locally owned stock by receiving them into remount farms.

It is satisfactory to know that owing to the care and trouble that was taken over this onerous duty, upwards of 24,000 animals were given back to their lawful owners at the end of the war. Many of the animals had grown out of all recognition, and many were only identified by the careful records kept by the officers in charge of the 'protection' farms."

It would seem that in the 24,000 have been included the 18,000 registered horses not removed from the custody of their owners. We are not told how many horses originally existed. The inner history of this calamity was evidently unknown to the writer of the above notice.

#### DEBILITY FARMS IN 1901.

The history of debility farms in the Cape and Orange Free State in 1899-00, has been given at p. 137.\* It has been pointed out that the Remount Department from the beginning of the campaign took charge of war-worn horses by placing them in their remount depots. When these could hold no more they hired farms, subsequently known as debility farms, into which the horse residue of war was poured, without inspection, and into places which did not afford sufficient support in the way of grazing for the number of animals placed on the farm. The year 1901 saw remount depots containing annexes full of disease, next door to, or even in contact with, the fresh animals from over sea. In addition, there were the debility farms, on which no remount horses were kept. Both places, as we have seen, were affected with mange and glanders.

\* See foot note p. 137 for other references, also pp. 132, 133.

It cannot be supposed that depots were deliberately infected, nor that they were infected through ignorance of the existence of the two above diseases. We have, therefore, to look at this question and ask why it was that a policy continued to be followed which the veterinary authorities before and during the war had pointed out could only result in disaster. The answer is brief, their opinion was not trusted. It was generally believed by the Remount Authorities that glanders did not exist in anything like the extent which the veterinary people stated: as the responsible officer said in conversation in 1901, "if it did we should hear more about it." As to mange, the notion widely existed that what we called mange was an affection of the skin which passed away spontaneously after the winter, and that it was therefore a trifling question. We shall examine the evidence on these points.

In a letter to the War Office dated 10th August, 1901, the Assistant Inspector of Remounts, says: \*

" . . . By the way you must not be alarmed at mange in this benighted land. Nearly every horse in Government or civilian hands which is left on the veldt in winter gets mange; the inhabitants take no notice of it, and it goes with the new coat; we put them through a disinfectant bath which kills it in a few times."

Such an opinion coming from the responsible head of the horse question in South Africa, was calculated to allay the natural anxiety which the returns of disease would create at the War Office; the information furnished to this body we may take to be the information supplied through the same channel to the Commander-in-Chief in the Field. For reasons which do not here concern us, veterinary opinion is not trusted until real difficulties arise. The casual observation or opinion of a layman belonging to the Staff carries more weight than expert advice, and this is not confined to veterinary matters only, though it is intensified in this case, as every mounted officer is given credit for knowing "all about a horse." The grounds for this belief are difficult to see; as a matter of fact, the layman who does know something of a horse is the most appreciative of veterinary advice. We see from the above that it was agreed to consider the question of mange as one of those trifling matters which the veterinary service had magnified into alarmist proportions.

As a matter of fact there is a disease of the skin affecting the native horse which is so like mange that it can scarcely be distinguished; further, as the Assistant Inspector of Remounts says in his letter, it is spontaneously curable, and it may be added is not contagious. These cases, however, did not represent the disease from which the over-sea horse was suffering; with them the psoropt could readily be seen in a warm sun, and the sarcopt by deeper scrapings and microscopical inspection. There was no doubt of the nature of the skin disease existing among the animals in the Field. From the

latter half of 1900 up to the time we are speaking of, it was parasitic mange of the above two types.

Regarding the Remount attitude towards glanders the evidence is equally convincing. Not only was the widespread existence of the malady denied, but it was openly stated that the Dutch and the Colonists looked upon our cases as those of "new sickness," a curable affection with which they had in recent years been rendered familiar. The opinion of a Dutch or Colonial farmer on matters of disease was a valued asset to the layman, who took it as his text and preached accordingly; unfortunately, in the matter of glanders, professional opinion was on their side. At least two Civil Veterinary Surgeons employed with the Remount Service believed that the cases condemned by their military brethren as glandered were not cases of the disease. One adopted the view that the cases were pyæmia, the other that it was the "new sickness" of the Dutch, which, according to them, is a non-contagious and curable affection.

With such professional views as these existing in the Remount Service, it is not difficult to understand how gladly they were given credence in discrediting the alarmist report of the military veterinary branch. The layman is always strongest in technical matters when he finds a divided house. The view of the non-glanderous nature of these cases grew and spread, in accordance with the natural desire of the Remount Department to make the best of matters; finally, when their case was believed to be at its strongest point, the Remount Department asked that an inquiry should be held into the nature of the cases which had so long been mistaken by the Army Veterinary Service.

Among the witnesses examined by the Court of Enquiry on Remounts was Lieut.-Col. Darby, a Deputy-Assistant Adjutant General serving on the Staff of Colonel Birkbeck. This officer, from June to September, 1901, was responsible for the Remount Depot at Johannesburg. In his evidence on "new sickness," Q.6567, he says:—

"They get a very heavy discharge. It looks like glanders, but a civil veterinary surgeon attached to the Remount Department said that the ulcerations were not of the same nature as glanders, and he was so sure of this that to prove it he inoculated himself. He did not get glanders, though he got a sore on his hand, and the military veterinary officers in the Field Veterinary Hospital still declaring it was glanders, Colonel Birkbeck asked to have a Court of Enquiry on those horses said to be suffering from glanders, but which the civil veterinary surgeon said it was only "snotsickta" (new sickness). They had this Court of Enquiry at Germiston; they killed four horses, but the results were indefinite. However, they declared it was glanders, and that the horses must be destroyed. But these horses recovered if left alone. Though they were not fit for anything for three months they got alright, and a glandered horse never gets alright. The civil veterinary surgeon who inoculated himself got alright also.

Q.6568. Did they apply the mallein test to the apparently glandered horses? A. Yes. With one of these horses when they tried the mallein test, the temperature instead of going up went down a degree. In the other cases the results were indefinite or not well marked."

We have quoted this evidence in full owing to its importance. It is the keynote to the belief of the

\* See Appendix F, C. of E. Rem., p. 368.

Remount Authorities in the matter of glanders. We do not intend to examine here the statements made by the witness, but may anticipate what has to be said of this matter in Part III., by stating that the Veterinary Committee appointed by the Commander-in-Chief directed the Civil Veterinary Surgeon to select his own cases of "new sickness" to bring before them. These animals were destroyed and on post-mortem examination found to be glandered.

The evidence brought forward as to the Remount views on scabies and glanders was the growth of many months. The Civil Veterinary Surgeon referred to in the above evidence had previously been in a Cape Depot, and he, and later another, had not only spread erroneous views as to the nature of the disease, but had discounted the opinion of the military branch on the growth and spread of glanders in Remount Depots and farms. Further, being the men on the spot, they were credited with knowing more about the matter than a man hundreds of miles away at the end of a telegraph line. Unfortunately, the "new sickness" and "pyæmia" opinions were listened to not only by the Remount Authorities but also by their administrative veterinary officer, under whose supervising professional care all remount depots and debility farms in South Africa (other than Natal) were placed. He knew that all of these were congested, and that the congestion increased every month; he knew disease was present, but apparently accepted the remount view of mange and the opinion of his civil subordinates on "pyæmia" and "new sickness." We do not urge this to condone what followed, though his depots and farms were hundreds of miles apart, and a man must to an extent depend upon the reports of those immediately in charge. But it was his duty to insist upon systematic periodical inspection of every animal on these farms, and to investigate the nature of the diseases ravaging them, to which so little importance was attached by the layman. There was no systematic inspection enforced or provided for; the officers' commanding farms and depots raised the greatest difficulties and objections to having horses caught up for this purpose; it occupied several hours of the limited staff they were allowed, and disorganised their work. This disorganisation was especially marked in Remount Depots, where, day and night, horses were being got ready to proceed to the front, or new horses landed. Further, the condition of the horse population of Cape Colony, see p. 185, had opened the eyes of the Remount Authorities to the number of animals available on the spot, and to the staff of the Cape Depots, already greatly overworked, fell the additional duty of travelling about buying.

Month after month of 1901 passed, and beyond the fact that these depots were congested and the farms full of sick, nothing was really known either of the nature of the diseases infecting them, or of the number of animals attacked. Monthly reports of disease, were called for, and after great

delay and difficulty obtained. It may seem hard to inflict further work on already overworked officers, but returns of disease are the only means of feeling the pulse of the army in the Field, without which everything is darkness. These returns let in light; pyæmia came to the front, and the appalling extent of mange was realised. The light-hearted manner in which glanders and mange had been regarded by the Remount Authorities was evidenced by the way they continued to pour thousands of horses from the north every month into the Cape Depots. The result of this was now about to be revealed. These horses for months had been coming from everywhere without inspection; they were turned out without inspection and remained out uninspected. By the middle of the year the returns of disease had made it possible to obtain an insight into the veterinary contents of Remount Depots and Debility Farms. The results were most disquieting. Mallein was directed to be used on the "pyæmic" cases, including those which were reported as having broken out again after being cured! Mallein reactions—frequently a difficulty in South Africa—were in these and similar cases repeatedly described as "not characteristic," or "might be produced by the irritating nature of the fluid." It was evident that the difficulties of mallein had not been studied nor its use fully understood,\* nevertheless, between February and August, 1901, 1200 clinical cases of the disease had been destroyed in one depot and its debility annex. It was an earnest of what was to follow. In September Major Blenkinsop, D.S.O., having been appointed S.V.O. Remounts, set to work to clean out this Augean stable.

Between September and December he caused

9000 cases of Glanders

700† „ Mange

2000 „ Debility, Injuries, etc.

to be destroyed in the Remount Depots and Debility Farms in Cape Colony alone, a total of 11,700 destroyed in less than four months!

During the above period, 2000 animals died in addition to the above. As evidence of the mass of disease, it may be mentioned that there were over 7000 cases of mange in these depots and farms in September, and between that date and December, no less than 17,000 cases of mange had been brought under treatment.

One might have thought that this stupendous calamity would have opened the eyes of the officers of the Remount Department, yet the evidence given above by Colonel Darby to the Court of Enquiry was tendered six months after the depots and debility farms of the Cape had been purged, and eight months after the Veterinary Committee sat which decided that the cases of so-called "new sickness" at Johannesburg were glanders in an acute form.

\* One C.V. Surgeon with the Remount Department was directed to keep his mallein in the dark and in a cool place. He buried it in the dung pit!

† There died in addition 248 cases of the disease.

Such is the blackest veterinary page in the history of the war. It demonstrates the dangers arising from hiding away large numbers of horses without adequate supervision and inspection, and it shows the want of veterinary organisation. Farms presented a fatally simple means of getting rid of war-worn and debilitated horses. Those with a knowledge of this class of work in the public service knew how easily horses turned out may be overlooked or forgotten, and, in the absence of strict supervision and periodical inspection, are bound to be neglected.

Not only is periodical inspection required to ascertain the progress made by the debilitated, but also to pick out those fit to take the Field again. Hundreds upon hundreds of horses clogged the depots and debility farms during 1901 that ought to have been at the front. Through want of systematic periodical inspection they were overlooked. Inspections are also required for another purpose, *i.e.*, the early detection of disease. Assuming an ideal system had been followed in these debility farms, and every animal carefully inspected on arrival, temporarily isolated, and then turned out when considered safe, even such a system as this does not relieve the administrative and executive officers from the duty of carrying out frequent inspections for the detection of disease and injury. It is the very life of the system, and neglect can only be followed by disaster.

The difficulties in the way of the Veterinary Service with the Remount Department in carrying out a sound system are not regarded as light. There was extraordinary pressure of work at the base on the arrival of horse-ships; landing and inspection of cargoes; inspection and despatch of animals to the front, and duties in connection with the purchasing of remounts. The farms were scattered over a sub-continent; the railway was unsafe, so that trains only ran during the day, which still further increased the difficulties where economy of time was of the utmost importance. Under these circumstances the tendency to trust to the men on the spot was perhaps natural. Two of these, by dire misfortune, held extraordinary views on the nature of glanders and farcy, and their attitude on the question not only assisted in the spread of disease, but also educated the Remount Department on wrong lines.

The layman interfering in technical matters can always, when he comes to grief, shelter himself behind his ignorance, but no such excuse can be extended to the professional man. The administrative veterinary service with remounts trusted too much to the reports received about the harmlessness of the disease, and leaned too heavily on its subordinates. The logical position in the public service is that if by so doing one comes to the ground, no sympathy can be expected, or error condoned, or there would be an end of all responsibility. The possibly extenuating circumstances we have urged would carry more weight if it could be shown that the debility farm easiest of access to the administrative centre was free from disease. Unfortunately, it was among the worst infected.

We again repeat that this work with debility horses had no right to be undertaken by Remounts, who possessed neither the knowledge nor the staff for carrying it out and whose hands were already full to overflowing. It should have been a distinct branch possessing its own lay and technical staff: but it was part of the policy of the Remount Department to allow nothing connected with the horse question to pass into other hands, and it had no belief at the end of 1899 and beginning of 1900, that the trouble foretold by the veterinary service would come true.

Though we have placed on the shoulders of the veterinary service the fullest measure of blame, we cannot shut our eyes to the evil genius of Remounts seen throughout; their light-hearted references to two of the greatest scourges of equine life, and the mixing together, from the first days of the campaign, of healthy and war worn animals, sound the key note to one of the greatest veterinary disasters of modern times.

"Debility" horses might have been found at almost any railway station on the lines of communication awaiting transmission to the remount department. Besides these, in the middle of 1901 collections existed at places provided by local commanders of districts, the existence of which was perhaps not even known to the Remount Department for some time. These places were without organization and under officers selected by the local authority as being for the moment out of employment. It would have required quite a distinct staff to go round and mark down the various collections of derelicts, and a still larger and highly organized staff to look after them. Yet it was of the utmost importance that every horse that could be salvaged should be.

With the Columns operating in Cape Colony there were depots where horses were taken in for rest and recuperation. All these were under General French and looked after by his officers. They contained many hundreds of debilitated horses, quite apart from those on the special debility farms. Similar centres were started by other Columns, but were at first unauthorised, and sometimes used as a means of hiding away horses against a rainy day, though most of them consisted of animals requiring a rest. Experience showed that these unauthorised collections were frequently bad owing to a want of proper supervision. In principle, the practice of distributing the sick over many small, rather than a few large, centres had much to recommend it, owing to the great difficulty of finding the needful grazing which was the essential factor towards recuperation. Towards the end of 1901 regimental rest camps were authorised for war-tired horses (p.196), and were an unqualified success, for the Columns were directed to leave men behind in charge of these horses, though the numbers in the Columns were correspondingly reduced. It is unfortunate that this system was not introduced earlier, but there were military difficulties, as at that time Columns could not spare the needful men

to look after them, and without these the horses starved.

One more feature in connection with debility horses may be mentioned. In addition to those kept for recuperation in Remount Depots and Farms, large numbers were sold and found their way to the ports, as no sales were allowed in the interior, after the experience of horses so sold finding their way into the hands of the enemy. These sales at Cape Town gave rise to considerable scandal, both in 1900, as mentioned at p.139, and again in 1901, and were finally forbidden owing to the cruelty inflicted, and the obviously unfit condition of these animals for work of any kind.

There was a feeling, however, among the civil population of Cape Town that with care and time the horses so rejected would recover, and the Colonial Government was induced to purchase a few hundred with the object of feeding them up, and showing the military authorities what could be done with the *débris* of war. It was not long before they found out, what we had already discovered, that once animals passed beyond a certain stage of debility they would die after lingering some time. The majority of the Colonial Government purchases behaved in this way, and in despair they invited the Chief Veterinary Officer of the Civil Department (Dr. Hueteon) to give them an opinion as to the best method of dealing with them. His opinion was that the only possible source of profit would lie in the Government buying 100 pigs and feeding them on the horses! This experiment is worth remembering, for the Government which bought these horses as a speculation had no intention of wasting public funds, but believed the investment to be a sound financial proceeding.

#### OUTBREAK OF CATTLE PLAGUE.

For some time in this History no reference has been made to cattle diseases; this, however, does not signify that the outbreaks of pleuro-pneumonia so frequently referred to at the earlier part of the war, no longer occurred. During the entire period which has been under review, pleuro-pneumonia and redwater were practically never absent, though by means of inoculation the former was kept under control.

We are now compelled to bring cattle disease under notice, as during 1901 the most dreaded of all plagues, "rinderpest," appeared during the height of the military operations previously recorded. It is not known how the disease became introduced. There is reason to believe that isolated cases existed in 1900. At p. 93 there is a note that as early as July, 1900, a disease which could not be distinguished from it was seen on the Zeerust road, among cattle brought in from Bechuanaland, and there were post-mortem examinations held in Pretoria in August of the same year, which were possibly cases of the disease. On 3rd March, 1901, cattle plague was reported in German S.W. Africa, 600 miles north of the Orange River. The fords

over this river were accordingly occupied to prevent cattle crossing. On 22nd April there were rumours of the disease in the vicinity of Mafeking; a month later it was reported at Ladybrand in the Free State, and on 6th August it was notified at Aliwal North, in Cape Colony. These latter cases were seen by expert officers of the Civil Veterinary Department of the Cape, who already had vast experience of the disease, so that the diagnosis was no longer doubtful. The anxiety which this outbreak occasioned was confined to the veterinary authorities; the military had seen too much of cattle disease to realise the gravity of the new trouble, and it was only with the greatest difficulty that any measures could be locally adopted to control the outbreak. Such measures are more than difficult in time of peace; in war they are quite impossible. It is obviously impossible to recast at a moment's notice the transport arrangements for troops in the Field, yet on the cessation of all such movements, together with isolation of contacts and destruction of affected, the control of the trouble depends.

By 15th August, 28 cases of the disease had occurred at Aliwal North, and others were reported 15 miles away. At this time there were 8000 Government oxen belonging to the Cape Transport Service, while the total number engaged in military operations throughout the area of the war was no less than 95,700. By 26th August 1000 cattle had been inoculated with bile against the disease at Aliwal under arrangements made with the Civil Government of the Cape, who started a bile station, but the disease was increasing; by this date 149 cases had occurred in Aliwal. At the end of the month the disease had reached native territory in the Transkei, due to loot cattle having been sent there for sale by the military authorities, in spite of the warnings which had been issued and the recommendations made. It may at once be said that in this matter of the movement of cattle, some Staff Officers charged with Transport duties could not be made to understand the extraordinary gravity of the disease; they had seen too much sickness among stock to attach importance to it, and were known to take local advice from the inhabitants instead of being guided by expert opinion. The spread of cattle plague in Cape Colony, and throughout the area of the war, was regarded by the rebel population as a blessing. It might bring the war to a close when other measures failed; even those not rebellious saw in it a prospect of material advantage, for the price of cattle would rise, while the unemployed, with some knowledge of the previous outbreak in the Colony, saw prospective employment as inoculators, and in other ways.\* On 14th September the disease had appeared far away on the west of the Colony at Kimberley; by the 25th the animals were dying faster than two veterinary officers (C.V.S's. E. R.

\* A man in military employment, an authorised inoculator, was found in 1902 to have sold bile at £10 a bottle!

Edwards† and Jelbart, now Capt. A.V.C.) could collect the bile. This outbreak was believed to be due to rinderpest stock being introduced among Government cattle by the enemy. The disease was also being spread, not only by military movements but by the traffic in bile for inoculation. A trader was convicted of having sold a few ounces for several pounds sterling, though the traffic in rinderpest bile was illegal. Wherever that man went with his bile a focus of infection was established. In spite of the extension of the disease it seemed impossible to impress the Transport Military Authorities with the gravity of affairs. Cattle from the Kimberley district were actually under orders to proceed to Malmesbury, close to Cape Town, a clean district 900 miles away, at a time when no less than 2000 cases of the disease had occurred in the Kimberley district. At Kimberley laymen had been provided with bile by the Transport authorities to inoculate cattle in a clean area! Again, local unskilled advice was acted upon, and even a Dutchman proposed to be placed in charge of a bile station! Dr. Hutcheon, the P.V.O. of the Civil Veterinary Department of the Cape, had warned the military veterinary authorities of the danger of using pure bile for inoculation, and the substitution of glycerinated. This warning had not been disregarded in the Cape excepting by lay authority. The danger of a little knowledge was very evident. A Transport officer at a large centre, learning that bile gave protection, did not realise that it was purely temporary, but believed that the animals so inoculated were "salted," and accordingly of greatly increased value. Animals so protected (?) were sent out with Columns and moved up and down the line, as it was believed they were safe.

By the end of October cattle plague had spread far north of Kimberley, in fact, even north of Mafeking, close to Rhodesia.

While all this was occurring the plague had gained ground elsewhere. In the Orange Free State it rapidly spread north and south from Ladybrand, through the movement of Columns. In the Transvaal both the west and the north were infected by the same means. In fact the whole area of the war was contaminated.

It can be safely said, so far as Cape Colony is concerned, that there were extensions of the disease, due to movements of cattle, which need not have occurred had attention been paid to the elementary principles of prevention urged by the veterinary service. The ignorant Transport conductor, often a Dutchman, the irresponsible advice of casual acquaintances among the civil population, and the prejudice of those who hoped to make something out of it, more often fitted in with the pre conceived notions of the Transport Staff, and were adopted accordingly. Nor was this confined to Cape Colony. The Transport Department at Pretoria was responsible for the spread of disease by means of loot and other stock they

wished to dispose of or move—movements wholly unconnected with military operations, and which, therefore, were not of an urgent, or at any rate, imperative nature. Nothing in the above remarks applies to military tactical movements; the whole is directed against movements which were not connected with the operations in hand, and generally amongst that class of cattle most liable to convey infection, *i.e.*, loot and impoverished stock. They are further directed against the unauthorised inoculation of healthy cattle with pure bile, and the utter, and sometimes wilful, disregard of veterinary advice by some members of the Transport Service.

It takes three months to prepare cattle plague serum; before the end of 1901 serum stations had been established at Aliwal North, Kimberley and Pretoria. A large bile station was also formed in the Free State near the focus of infection. From December the control of the disease became possible. The machinery employed will be dealt with in Part III., but without the skilled assistance of the Civil Veterinary Department of the Cape under Dr. Hutcheon and Mr. Borthwick, and of Drs. Turner and Theiler in the Veterinary Laboratory at Pretoria, it would have been impossible to deal with this scourge, which, be it remembered, was actually fought and controlled in the middle of active operations. This, indeed, is a record, and a triumph of science; it is the highest tribute which can be paid to the genius of Professor Koch.

In the following table the strength in round numbers from March to December, 1901, of the transport oxen in South Africa is given, together with the number of casualties. To appreciate the difficulties of dealing with such a disease as rinderpest in war, it must be remembered that the thousands of animals representing the monthly strength of the transport, were more or less constantly on the move.

	Strength	Deaths
March	66,600	?
April	76,400	1800
May	85,800	3700
June	96,900	7800
July	96,000	10,700
August	95,700	16,200
September	86,700	16,300
October	78,500	14,500
November	73,000	9700
December	71,200	9000

These strengths are of military transport only, the property of the public, and do not include the protection or loot stock, which at times, together with sheep, rose as high as 200,000. These animals, as will be explained in Part III., were placed on various farms throughout the area of hostilities, some eighty places being selected for their accommodation. The mortality amongst this class will never be known.

Over 8% of the transport oxen were dying in June, mainly for want of food, from exposure during mid-winter, and pleuro-pneumonia. In July the death

† Now Board of Agriculture.

rate was over 11%. In August, when rinderpest had a firm hold everywhere, 16,200 animals died, nearly 17% of the strength; rather more died in September, or roughly 18%; in October it was 17%, and in November and December, at which time an impression had been made on the disease, the mortality fell to under 12%. These appalling figures give some notion of the severity of the outbreak, and the additional work and responsibility cast upon an already over-burdened and small veterinary staff.

During the time we are speaking of, and later, not for one moment was the military position altered by the animal plague which had broken out.\*

\* The Commander-in-Chief in his despatch of 3rd Dec., 1901, refers to the military operations of 8th Sept.-8th Oct. being somewhat impeded by the prevalence of cattle plague. He adds that the disease was spreading, likely to make itself felt in every district and to cause great loss. To counteract this, he refers to the measures for inoculation which, by

Columns still kept the field, the enemy was pushed and pressed, and the disease in this way carried broadcast over the land. There must have been many animals surviving from the last outbreak whose immunity was still secure, and there were thousands inoculated. The whole of the transport and loot stock, the latter numbering tens of thousands of animals, were protected, the bulk of this work in the Transvaal and Free State being carried out under the supervision of Lt.-Colonel Flintoff and Major Sharp, A.V.D. The special work of the latter officer will be brought to notice in Part III.

throwing the animals out of work for a week or two, considerably reduced the efficiency of the ox transport for at least a month. In his despatch of the 8th Dec., he says that rinderpest is still raging, but that the process of inoculation and the care taken of uninfected animals have combined to prevent the movements of the troops from being seriously interfered with. In the above despatch he adds that "the successful coping with the disease has surprised the old inhabitants of the country."

1902

ORANGE FREE STATE.

OPERATIONS IN THE SOUTH AND WEST.

JANUARY-FEBRUARY, 1902.

The last reference to fighting in the Southern Free State was made at p.174. The operations continued to be of the "clearing" character, and later, C. Knox, who still commanded in the south, "drove" up the eastern side on to the block-house line Thabanchu-Ladybrand, but hardly a living thing was met. This observation shows how rinderpest was spread by the movements of Columns, for it was through this area it had travelled from Ladybrand to the Orange River. Meanwhile, matters on the south-western side of the Free State had suddenly become very active, and Rochefort's five columns were sent back (p.174) and raided between Philippolis and the Modder River, though not always with success. The transport of one of his columns was captured and entirely destroyed on 25th December,\* and another column, that of Du Moulin, was attacked on the night of 27th January, the camp "rushed," all the horses, 91 in number, lost by fire, together with 120 mules. The losses among the men were correspondingly heavy, and included their gallant leader.

Early in February Rochefort went north from Fauresmith to Boshof, and there combined with Sitwell. The latter had an independent column which raided Griqualand. On 13th January it had a sharp encounter with the enemy 80 miles east of the Modder River, and suffered many casualties. On 5th February it reached Kimberley, and on 16th was again engaged, with many casualties. Rochefort's journey north was due to this, but the opposition disappeared.

OPERATIONS IN THE NORTH-EAST FREE STATE.

ELLIOT'S BIG DRIVES.

JANUARY-MARCH, 1902.

We last saw Elliot's force at Lindley in December, p.177, replenishing after the vain effort to obtain touch with De Wet subsequent to Tweefontein. Elliott was out again in the course of a day or two scouring the oft-travelled road to Reitz; then north towards the Vaal to the block-house line; then back

south through the Liebenberg's Vlei. There was no sign of the enemy, and Lindley was again made for, as the troops by now were on reduced rations. He arrived there on 4th January, having covered 60 miles that day, and, in five days marching, had travelled nearly 250 miles. Particular attention is drawn to this remarkable marching, which, as the "Official History" remarks,† is "a feat which the most brilliant rewards have seldom been able to extract from troops, especially under service conditions of such rigour." These marches were not performed by a handful of picked men, but by a mass nearly 5000 strong. Fifty miles a day for five successive days! Supposing that the Cavalry Division under French, which left Ramdam in February, 1900, had been composed of conditioned well-fed horses, what might it not have effected? Elliot's losses from exhaustion in these marches are unknown, they were doubtless heavy. The marches stand out as the most remarkable distance rides under service conditions ever executed by a large body of mounted troops, the difficulties being intensified by an African midsummer. Elliot was a good horsemaster; his subordinate Commanders included men who not only understood this art, but also that of living on an enemy's country.

After only two days' rest for his tired men and horses he once more left Lindley owing to the presence of De Wet, who was moving west to cross the line. The following day, the 8th, De Lisle and Fanshawe came in contact with the enemy; by means of a 50-mile march they retained it, and compelled De Wet to fall back to the east.

Everything now depended on keeping De Wet on the move. Elliot's force required a rest. Byng, who had been resting close to Lindley now moved on Reitz, and was joined by two other columns, Garratt's and Dunlop's, returning from block-house line construction. By 20th January these were massed, and drove up and down the Liebenberg's Vlei, but with no success. Four more columns now appeared: Barker from Winburg, Dawkins from Harrismith, Rawlinson from Standerton, and Rimington from Frankfort. Elliot, in the course of a day or two, was rested and able to move, and the whole mass of columns swept south-east towards the Harrismith-Bethlehem block-houses, Byng being left behind near Reitz.

De Wet all this time was within the area traversed by the troops, and on 1st Feb. intended to move south in the direction of Winburg out of the block-house area. He issued instructions for his Commandos to assemble between Heilbron and Reitz, and a Commando near Byng, in endeavouring

\* The "Official History," vol. iv., p. 430, records that three of the native drivers of the transport were shot in cold blood. Some of the prisoners were stripped naked and compelled to walk in this plight more than 30 miles across the burning veldt. Such punishment has to be witnessed to be realized. It was Midsummer, and the sun acts as a cautery on those parts of the body which are always protected.

† Vol. iv., p. 399.

to carry out its orders was attacked with vigour, and the guns taken at Tweefontein re-captured. Meanwhile another drive was being organised, and De Wet and his following were to be driven west by the forces now near Harrismith. Accordingly, the mass then turned about and first deployed along Liebenberg's Vlei for fifty miles, then faced west. On the night of 5th Feb., 9000 men were covering a line 80 miles in length; \* their duty now was to maintain this line day and night "over country which was often broken by intricate hills and screened by rushing torrents," constituting "a feat of discipline, endurance and skill, which, as far as we know, is unparalleled in the history of war."† The railway was 50 miles away, and the time to be occupied in searching and driving this strip of country was three days and two nights. The ends of the driving line rested on block-house lines, and were supported by other columns which were to "cut in" as the gigantic crescentic line of horse-men advanced. The railway block-house line had been strengthened by additional infantry, seven armoured trains patrolled it, converting night into day by their search lights, and a battalion of Mounted Infantry lay available to gallop to any point at a moment's notice.

The skill required in bringing this extraordinary military engine into effective being shows what good staff work is capable of effecting. Not only had this mass of horses to be assembled and then spread out so that contact from one end of the line to the other was never lost, but man and horse had to be fed as they stood in line, and the food supply to be on the spot exactly where required.

De Wet and his following of 1800 were in the net; he was accurately informed from without by heliograph of all movements, and his openly expressed contempt for block-house lines was about to be tested. He directed his men to break out where they could. He determined to rush the block-house line. The cordon which surrounded him and his stalwarts on the morning of 6th January consisted of 300 block-houses, seven armoured trains, and 17,000 men;‡ "not one of whom was to be off duty for three days and two nights. ||

De Wet with 700 men marched south on the 6th while it was light, and by midnight had reached the wire fence of the south (lateral) line of block-houses without arousing suspicion. The pitch dark night served him well; the wires were cut and his whole force was across without the inmates of the block-houses being aware. He was followed by 600 head of cattle which rushed the fence and drew fire with but little loss. He continued his march for 40 miles and reached the Doornberg. The northern (lateral) line of block-houses was burst through by

another party who suffered some loss. Meanwhile, on the morning of the 7th, the vast line swept forward towards the railway line of block-houses; as the day wore on the excitement increased, for many of the enemy were known to be in the cordon. As night approached "Precautions were redoubled; every obstacle that ingenuity could invent was improvised; the last reserves of ammunition were distributed and their lavish use enjoined; scarcely a soul slept. All night long without intermission the rifles crackled up and down the line; all night long the searchlights of the armoured trains could be seen to the north and west flashing broad white beams over the dark veldt; and all night long, outnumbered by forty or fifty to one, the peasants of this indomitable district scoured the deadly cordon searching for a hole or cranny of escape, their dark figures silhouetted against the glare of the searchlights."\*\* By the evening of the 8th the total killed, wounded or prisoners numbered 286, but, as we have seen, De Wet was not amongst them.

#### ELLIOT'S SECOND DRIVE,

##### LANGVERWACHT.

FEBRUARY 13TH TO 27TH.

The first drive was barely over when preparations for another on a much larger scale were made. In the first operations only the centre of the North-east Free State had been swept from east to west. The circumference was now to be dealt with. The North-east Free State is an irregular square bounded on the east by the Drakensberg, on the west by the block-housed Free State Railway, and on the north by the Vaal. In the present operations a portion of the Transvaal was included, so that the north line was the block-housed railway running from Johannesburg to Natal. The southern line of the square was the block-house line running from Kroonstad to the Drakensberg. The first movement was to occur south of the block-houses, as far, indeed, as the Doornberg close to Senekal, whither De Wet had proceeded. The space to be swept was 340 miles in length, and varied from 50 to 60 miles in width. Three sides of the square had to be dealt with, swept from opposite corners simultaneously by a northern and southern group of columns. The southern group having reached Harrismith was to line up almost due north and south, and hold the 65 miles of the Wilge River lying between a point 20 miles south-east of Frankfort and Harrismith. The northern group of columns sweeping from the Free State-Johannesburg Railway, on both banks of the Vaal, was to travel east until a point 20 miles south-east of Frankfort had been reached, when the whole line of troops, now 35 miles long, would wheel south, still hugging the Natal Railway up to Paardekop, where additional troops were to join owing to the increasing length of the line. The enemy should

\* Roughly the distance from London to Peterborough.

† "Times History," vol. v., p. 471.

‡ "Times History," vol. v., p. 478.

|| Among Rimington's other instructions to his Column appears the following:—"Every man from the Brigadier to the last native to be on duty, and to act as sentry for one-third of the night."

\* "Times History," vol. v., p. 480.

now be contained between the Drakensberg on the east, Elliot and the Wilge on the west, and kept in this area by the southern line of block-houses from Harrismith to Van Reenan's Pass, while the northern group of columns drove them south on to this block-housed line. The latter was temporarily strengthened by six columns and all the permanent troops of the district that could be placed in position. These details are necessary if we are to understand what was expected from the animals, on whose efforts success depended.

The movement began on 14th Feb., the troops having been given a few days' rest after the first drive. In fourteen days the operations were to be completed. The bulk of the work fell to the northern group of columns, represented by Rimington, Byng, Rawlinson, and later, Dixon from Paardekop. The southern group under Elliot consisted of De Lisle, Fanshawe, Holmes, Marshall, Lawley, and Du Cane, the two latter being fresh columns. There is nothing to record of the movements of this vast and complex machine between the 14th and 23rd February. Meanwhile, De Wet, who had retired to the Doornberg after the first drive, had actually re-crossed the block-house line—with loss—and deliberately placed himself within the area cleared by the first drive. The group of southern columns lining up on the Wilge drove him and his force in the direction of Reitz, and here he met President Steyn. "The two watched for a time the oncoming of the tide of troops which lapped without a break over every horizon. Soon they had to be gone, for Elliot was bearing down on the Wilge. On February 22nd they sidled away up the Cornelis River with eyes on every side, falling in continually with groups of burghers who were flying in all directions from one danger to another."\* De Wet, who was now enclosed, determined to break out to the north, and with President Steyn and 800 men they forced the cordon of troops on the night of 23rd of February at Kalkrans on the Hol Spruit, at a weak point between the columns of Rimington and Byng. The action is known as *Langewacht*. The enemy charged through the thin line, rolled it up from end to end sufficiently widely for their purpose, and under a desperate fire the whole mass of 700 men, the Government with De Wet and Steyn, and led horses, got through. They inflicted severe loss on the 7th New Zealand M.I., who lost 58 killed and wounded, while 80 horses belonging to the enemy were lost. De Wet lost everything in the way of transport and cattle. On 27th, the last day of the drive, 778 prisoners, 50 of the enemy killed, 25,000 cattle and 2000 horses were the total result of an operation which will always be remarkable in military annals.

#### ELLIOT'S THIRD DRIVE, MARCH 4TH TO 13TH.

Three days after the operations last described a further elaborate drive was projected from the

point where the various columns had now been brought together. Elliot with nine columns, total 10,000 horses, was to sweep north on a front of 30 miles in a reverse direction to that traversed by the northern group of columns during the last operations, until he reached the Frankfort-Botha Pass block-house line. The other and smaller sections of the force, consisting of 5500 horses, were to march north-west across Elliot's rear and form an oblique line 30 miles long, the left end of which was to rest on Lindley. The second stage in the operations was for Elliot's northern force, now on the block-house line, to turn about and wheel to its right, so that it came into line with the southern force still resting with its extreme left on Lindley. The combined forces were then to advance westward in one long line, Lindley-Frankfort, and close in on the railway. Elliot started north on 4th March, and reached his first position on 8th. The southern column started on the 5th. On the 10th the two forces, now in the second position, moved westward in one long line across the north-east Free State towards the railway. The drive was over on the 13th, and the results were very poor. As early as 5th March De Wet had escaped westward across the railway line, and was now on the opposite side of the Free State. He rushed three block-house lines with but little loss. In front of the driving line on the 10th was one Commando which, on a front of 60 yards, deliberately charged the block-house line, trampled it down and escaped. During the above operations four columns dropped out, being withdrawn during the first stage to strengthen the Western Transvaal forces in a series of disasters yet to be considered.

At the end of the drive, Rawlinson's force was withdrawn to join with Basing's column from the North-west Free State in search of De Wet. Owing to wet weather it had a very bad time after crossing the railway, and found itself at Klerksdorp on 21st March without learning anything of the fugitive.

#### WESTERN TRANSVAAL.

##### YZERSPRUIT, TWEEBOSCH.

FEBRUARY—MARCH, 1902.

We have reached a point in this history when the military operations have undergone a very great change. We have traced them from the time when battles extended over miles, and the backbone of every operation ultimately rested with the infantry. We have seen how the army became transformed from one on its feet to one which was mounted, and some of the difficulties attending so radical a change have been drawn attention to in connection with horse wastage. We have watched the operations become so altered in character that, instead of employing vast bodies of men, numerous almost microscopic forces were the only means of coping with the situation, and finally the employment of hordes of mounted men literally sweeping a sub-Continent in a long thin line. With the

\* "Official History," vol. iv., p. 426.

enemy the educative influence of these changes was not neglected. Side by side there grew up in him one equally great; he no longer clung to cover or waited to be attacked, but showed himself with boldness and attacked when it suited his case. Long months of campaigning had given him the confidence which he at first lacked. Mobility he never lost. We have now to see the highest expression of the change in his tactics, the resolute attack of large masses advancing at a fast pace and distracting their enemy by fire from the saddle, and impetuously riding over them.

Every one of the tactical changes evolved during the campaign found its reflex in the altered conditions under which the animals had to serve. It began with a sudden and enormous increase in mounted riflemen untrained to the care of animals. Next followed changes in the artillery, fewer horses being required as guns were reduced in number. Then mobile columns came into play, adding vastly to the number of animals and to the casualties. Later their complement, the block-houses which, by protecting transport, enabled the services of the slower moving ox to be more fully utilised, though later the ravages of rinderpest had seriously affected this admirable source of energy.

The impressive drives wore down vast numbers of animals by the enormous distances covered, while the night raids proved their salvation by allowing the day for feeding and rest. We are now at a period when the day and the night were both utilised for mounted operations of almost unparalleled magnitude. The horse had once more fallen on evil days, and the unmanageable numbers of sick which resulted, looked at first sight as if the veterinary service had learned nothing from over two years experience in the field. It will, however, be shown that the sick resulted from neglect of the elementary fact that horses require time for both food and rest. Though men are saved great physical exertion by being mounted, the greater mobility given them does not decrease the period required by the horse for feeding and recuperation.

We last saw the Western Transvaal in January. (p. 182), where, for the three previous months owing to the activities in the Eastern Transvaal, Orange Free State, and Cape Colony, but few columns had been operating in this area. It suited the tactics of the enemy to burst out and die down, apparently remaining extinguished, but in reality only resting men and horses for fresh efforts later on. The burgher became as weary of Commando as his opponent did of Columns. The one, however, could dissolve at will and rest securely, while the other was kept continuously at work, passing in a day and a night from one theatre of war where his presence was no longer required, to a distant one where the smouldering fire had broken out afresh. Men and horses grew stale under the conditions of continuous warfare. The *clash* and dash of the enemy during the latter stages of the campaign were due to the beneficial effects of rest on both men and horses.

For five months matters had been relatively very quiet in the Western Transvaal, and opportunity was taken to push on with the construction of block-house lines. The latter, in the Western Transvaal, were not so numerous as elsewhere. Pretoria and west for 60 miles was enclosed in a wire fence. Johannesburg, Krugersdorp, Frederickstaad, Potchefstroom, Klerksdorp and Vereeniging lay within another fence. Mafeking, Lichtenburg, Wolmaranstad and Vryburg were points in the circumference of an immense area surrounded by wire, but not sub-divided as had been found necessary in the case of the North-east Free State and the Eastern Transvaal. Practically the whole northern portion of the Western Transvaal was untouched by fencing. The great tilting ground of Methuen and De la Rey, lying between Mafeking and Rustenburg, still lay exposed. The scene of all the subsequent operations in the Western Transvaal was confined to its southern end lying between Lichtenburg in the north, to the Vaal on the south, and from Klerksdorp on the east to Vryburg on the west, roughly a square with sides of 120 miles.

In the early days of February Methuen left the Field. For two years he had been incessantly marching, during which time he had covered some thousands of miles.\* The command of the Column now fell to Colonel Von Donop, whose orders were to occupy Wolmaranstad, and using this as a base operate in the surrounding district. Wolmaranstad had to be supplied from Frederickstaad, fifty miles away, and no difficulties were encountered with the first Supply Column which left early in February.

The second Convoy left for Frederickstaad on 25th February, it consisted of 145 mules and 6 ox waggons, with an escort of 480 men, of whom 250 were mounted. On the morning of 25th Feb., the convoy was within fifteen miles of its destination, and had started before dawn with four waggons abreast so as to reduce its length. At this moment it was surrounded by a powerful Commando under De la Rey, who developed the attack at *Yzerspruit* by a volley in the face of the Column, which sent panic-stricken mules to the rear; but the rear was simultaneously attacked, and from both ends a fine defence was made. The enemy, employing the charging tactics, came up over and over again only to be beaten off. But the next stage of De la Rey's scheme had yet to be carried out; he had arranged for a third Commando to strike the flank of the Column, and after some delay it rode up and delivered its attack at the gallop, but was driven off. For two hours longer did the Column hold out, until ammunition failed; 187 men were killed or wounded, 170 horses and 1450 mules killed or captured, and 2 guns lost.

\* The late Major Crow, A.V.D., accompanied him in all his marches as S.V.O., until retired for age early in 1902. Like his chief he never tired.

Kekewich was on his way to Klerksdorp, together with Hickie's (now Grenfell's) force, when, at Hartebeestfontein on 25th, he heard of the loss of Von Donop's Convoy. He at once made for Wolmaranstad, which he reached on 28th. He was there joined by Yeomanry sent out from Klerksdorp. A Flying Column under Grenfell, 1823 horses, was also sent north to look for De la Rey. Kekewich evacuated Wolmaranstad and arrived at Klerksdorp on 4th March, and Grenfell after a fruitless search returned to Klerksdorp on the same date.

Lord Methuen at Vryburg, hearing of the disaster to part of his late Column, at once organised a force to attack De la Rey. In view of what occurred, it may be well to say that the force he scraped and raked together was a mixture from fourteen different units, and consisted of Paris' "Kimberley Column" (which we have not met with since the invasion of the Colony by De Wet), together with whatever could be laid hands on, the force eventually numbering 1200, of which 890 were mounted troops, mainly untrained Yeomanry. Attached to Paris' Column was a Mobile Field Veterinary Hospital under Civil Veterinary Surgeon D. T. Tamblyn.\* Methuen left Vryburg on 2nd March, travelling north-east through a badly watered part of the Transvaal, and made for a point ten miles south of Wolmaranstad, where he expected the Column under Grenfell to meet him. On the 6th March, Methuen had arrived at his camp at *Tweebosch*, lying in the angle formed by the Great and Little Hartz River. He was still 25 miles south of his objective, and, though he did not know it, Grenfell was 36 miles south-east of him. Between Grenfell and Methuen was De la Rey with a powerful Commando.

On Jan. 7th Methuen's Column moved forward, the transport being in front (the ox before the mule in order to regulate the pace). An attack from the rear was expected, Methuen having been warned the previous day that De la Rey was in the vicinity. It was still dark, and for two hours the slowly moving mass crawled along. Behind was De la Rey with 2000 men, probably the pick of the Federal Forces, following stealthily in its tracks, and waiting for the first streak of dawn. At 5 a.m. a crash of musketry burst on the rear and flanks of the Column, the ox waggons were halted, and the mule waggons directed to close up, but the majority dashing ahead passed the ox convoy and went racing over the level and unbroken veldt away to the north. Nor was this the only panic; the bulk of the mounted troops guarding the flanks and rear also galloped forward and deserted the guns and convoy,† and the enemy galloping down in their new style poured a terrific fire into the mass from both sides. The gunners who had opened fire were ridden down and destroyed to a man. Around the

ox waggons Methuen placed his infantry, and for two hours these sustained an unequal combat under the inspiring influence of their General. Another small portion of the force, composed of stalwarts, took up a position under Paris in a Kraal about a mile ahead. The fight raged at point blank range, and when the Northumberland Fusiliers ran short of ammunition, an unknown man,\* bearing a charmed life, made several trips with boxes of ammunition from the waggons, and distributed it along the bullet-swept line. It was Civil Veterinary Surgeon Tamblyn.† The party of forty in the kraal fought on after the Convoy had succumbed, and nothing but field guns compelled them to yield, their defences being knocked to pieces by shell fire. In five hours nothing remained of this Column but the killed, wounded, and prisoners (68 dead, 132 wounded), 240 horses were also killed and wounded.

Then followed acts of murder which had become all too common; native drivers were shot, and the whole Indian and Kaffir establishment of the Field Veterinary Hospital were butchered. One Farrier Sergeant of Indian Native Cavalry and two Indian Veterinary Assistants (men carrying no arms) were ruthlessly shot dead after the surrender, and nine Hospital Kaffirs were either killed in action or murdered later.‡

We have entered more fully than usual into the account of this disaster, not only from its intrinsic interest to the veterinary service, but also from the fact that it created a feeling well nigh to consternation, and determined the Commander-in-Chief to concentrate his forces in the Western Transvaal in order to exact reprisals. Henceforth, Klerksdorp was to be the busiest place in any theatre of the war; the action of *Tweebosch* had shifted the whole centre of gravity of the campaign.

Grenfell knew nothing of the disaster at *Tweebosch* until the following day; he then fell back on Lichtenburg in case the garrison there should suffer the same fate. But De la Rey went south and met Steyn and De Wet (who had just passed through the ordeal related at p.211) at a point between Wolmaranstad and Klerksdorp.

\* See *Standard*, 14th April, 1902, whose correspondent describes this gallant act as being performed by a "veterinary surgeon whose name I failed to gather."

† Had this action been successful, it can hardly be doubted that C.V.S. Tamblyn's devotion would have been suitably rewarded. Two horses were killed under him early in the fight, and he was captured but escaped, to be again taken at the surrender.

‡ General De la Rey, the most chivalrous of foes, was in no way responsible for these acts of murder. His young men were the offenders, and it was impossible for him to be in all parts of the field at the same moment. That he knew of the tendency is certain, for the "Times History," vol. v., p. 507, records the fact that he flogged several of his men for rough treatment of prisoners captured at Yzer Spruit. It also states that while he was talking to Methuen, who was then lying severely wounded, a burgher began to remove the gaiter from the unwounded leg under the eye of De la Rey, who personally and forcibly intervened. We have also seen, at p. 180 of this History, what occurred at *Kleinfontein* at the hands of the same men.

\* A Canadian Graduate, now Dept. of Agric., Canada.

† "Of the panic of the majority of the mounted troops, lack of training, insufficiency and inexperience of officers, and above all the heterogenous nature of their composition were the main causes."—"Official History," vol. iv., p. 420.

*ORANGE FREE STATE.*

OPERATIONS MARCH-APRIL, 1902.

*ELLIOT'S FURTHER DRIVES.*

The drive by Elliot obliquely across the Free State which terminated on 11th March was not the last, in spite of its relative unproductiveness. Five columns, Elliot, Barker, Garret, Rimington and Nixon, containing 12,000 horses, were to sweep across the Free State from west to east in one long line, each end touching the block-house lines, which were fifty miles apart. The movement was to be deliberate, and there were no long marches. The operations after passing the Liebensberg Vlei—which is the long central gutter of the north-east Free State lying between Frankfort and Bethlehem—were to depart from the usual programme. A force was to go ahead, followed by a second, these were to do the needful pounding, while a third in the rear was to act as a net, and prevent all escape by closing in up to the Drakensberg and compelling fight or capture.

As early as the sixth day after the previous drive the troops were getting into position, a very short rest for leg-weary horses, and the general operations started on the 19th March. The advance was made from the line Heilbron-Doorncloof, points nearly forty miles apart. Heavy rain night and day did not promise well for the conditions likely to be met with at the foot of the Drakensberg Watershed, which was 100 miles away, and where the operations were to terminate. By the 26th March all but one of the columns was lying between the Liebensberg Vlei and the Wilge River, now both roaring torrents. No means existed for bridging the river. The one column on the eastern bank of the Wilge could not advance without support, and moreover could get no food until supplies reached them by improvised raft on the 28th. The condition of the horses during this time was seriously affected. Rain and cold on empty stomachs made many victims. The Wilge did not fall until 1st April; in the meantime the enemy had had four days in which to scatter. The passage of the river was mainly by swimming, while the transport had to go miles out of its way to cross by the few existing bridges. On the 2nd April it was known that the enemy intended to break through the cordon that night. It was pitch dark and raining, and for some hours before midnight hoof sounds were heard which drew fire; to patrol was impossible. A wire fence ran along the front of the line. "Suddenly at 1 a.m. two trumpets rang out close in front of the line, and immediately after a mob of mingled Boers and cattle burst against the wires and endeavoured to force a breach. The stout strands, and the heavy fire which poured through them were too much for many of the Boers; but at one place in the fence the weight was irresistible. The wires snapped, the nearest picquet was swept away, and some hundreds of horsemen poured over

the place and galloped westward into freedom." \* The results of this drive, which terminated on 5th April, were very disappointing, 76 prisoners and 4800 cattle and horses.

The Columns were now dispersed, those of Nixon and Garret went north, crossed the Vaal and joined B. Hamilton in the Eastern Transvaal, Nixon being sharply attacked before he crossed the river. Elliot proceeded to Harrismith, and from there his Column under Barker marched to Frankfort; Elliot with his remaining Columns traversed the country north-west, passing between Reitz and Bethlehem. He was attacked on this journey, and reached Lindley on 21st April after a month's hard work.

On arriving at Lindley, instead of getting rest the Columns were ordered to march back and make Bethlehem their headquarters, with a view to clearing the Brandwater basin which was now a source of trouble. A week of reconnaissance followed in this mountainous region, at the end of which time Elliot was withdrawn for a combined drive under Bruce Hamilton which we will mention later.

Attention is directed to the continuous work performed by these Columns under Elliot. On the basis of all previous observation it would result in 3000 sick horses a month; as a matter of fact the inefficiency would be below this, for the work was relatively steady, and the general returns of sick were already showing a reduction in numbers. Nevertheless the number of sick was enormous. There were 31,000 horses employed by the thirty Columns alone operating in the Free State, and at the lowest estimate these must have furnished 6000 sick horses a month, including 1,500 died and destroyed. In addition to furnishing a veterinary service for the care of this multitude of sick, it must not be forgotten that rinderpest was still rife and pleuro-pneumonia ever present. Tens of thousands of animals had to be inoculated against these diseases.

*CAPE COLONY.*

OPERATIONS JANUARY-MAY, 1902.

The operations described at p. 181 had relieved a great deal of the anxiety felt for the safety of Cape Town, but the situation was by no means satisfactory. Maritz had been driven towards the north-west, but Smuts was present in supreme command, and was unlikely to take quietly the rebuff his schemes had experienced in the Cape Peninsula. In order to deal with him and his Commandos the long block-house line from Victoria West to Lambert's Bay was projected. The matter has been referred to at p. 181 as one of the most remarkable undertakings in this class of work; 320 miles of wire fencing and block-houses were to be constructed through districts little better than a desert. The line we have seen was begun at both ends simultaneously, and pressed forward with such rapidity that in a fortnight Lambert's Bay had been

\* "Times History," volume v.

connected with Clanwilliam, and had thus interposed an obstacle on the road to Cape Town. At the Victoria Road end matters were slower, the constructional difficulties being due to the unsuitability of the animals employed in transporting the material. The country consists of karoo bush and sand, it is sparsely populated owing to its small rainfall; there sheep and goats thrive, but cattle die, and the only animal used for transport purposes is the donkey. A donkey convoy is excellent if given time, but it must move at its own pace, and that was considered to be too slow to meet the urgency of construction. Ox transport was therefore introduced into a country where no keep for oxen exists, and a large depot was established at Victoria West. It will be more convenient to look at this depot after describing the operations which took place during the construction of the block-house line.

The wire fence from Victoria West to Lambert's Bay was north of the Cape Town railway, and generally speaking about 130 miles away from it. Smuts could see that if erected it would help to deny him access to a piece of country 320 miles long by 130 wide, but he also knew that if it were to be constructed the Columns protecting it could only be fed from depots established much nearer to the scene of operations than those on the Cape Town railway. Such depots were established at Calvinia, Sutherland and Fraserburg, and were being filled up by convoys protected by the various Columns. In the western part of the area were the Columns of Wyndham and Kavanagh at Clanwilliam, and that of W. Doran, lying in an entrenched camp midway between Sutherland and Calvinia. At the eastern end were the Columns of Crabbe, Lund, Capper and B. Doran. While Clanwilliam was busy filling up Calvinia, the Columns engaged in this operation were repeatedly attacked during February by Smuts. On the 5th February W. Doran left his camp to attack a party of the enemy, and with difficulty held his own; on returning to camp he found it had been attacked during his absence, and all his waggons burned, though he arrived in time to save his mules. So considerable were his losses that he had to return to the line to refit. Sutherland was filled up by a convoy under Lund which followed Capper, and both entered the place on 25th January. Crabbe was to provision Fraserburg, and at this moment was filling up with supplies at Beaufort West. The enemy under Malan was lying between Sutherland and Fraserburg, and denying the road to the latter place. Crabbe left Beaufort West, and on nearing Fraserburg on 3rd February he, for safety, left his convoy of 100 waggons behind him. His convoy was destroyed on 5th, while he suffered heavy loss and was saved from possible obliteration by the arrival of Capper and Lund from Sutherland. All the animals in his donkey convoy were lost, and he returned to the line to refit.

The operations just referred to were part of the counterstroke devised by Smuts. He had massed

some of his Commandos against the Clanwilliam group; these were under his personal command. Others under Malan he had placed between Sutherland and Fraserburg, while a force under Maritz had been sent 280 miles to the far north-west to attack Ookeip in Namaqualand. The latter does not concern us at present. It was now decided to "drive" the space containing the forces of Malan, and four Columns set out from the railway north of Beaufort West at various periods between the 17th and 23rd February, and drove for 100 miles towards the wire fence, Williston-Carnarvon-Victoria West. They cleared the area between Williston and Victoria West. The Commandos either breaking out north through the fence, or keeping within it, doubled east, attacked the block-housed railway and crossed the line, thus entering once more the midland area. The party under Malan accomplished this on 21st February, and was at once followed for several days by the Columns of Wormald. On 1st March, Wormald was relieved by B. Doran who, for a fortnight, continued the chase of Malan up and down the midlands, when he had to go to the line for rest and supplies. Malan also needed a rest and retired to the old haven of refuge in the Camdeboo Mountains. Here he met Fouché and Wessels, who were being chased by other Columns from the north-east, and the result of this meeting will be noted later.

During the remainder of the war the Columns north of the Cape Town railway were mainly engaged in keeping the block-housed area clear of Commandos. Capper, holding a central position at Williston, was frequently engaged during March and April pushing back L. Wessels and Theron. Prieska, to the north of the block-house line. This place, simmering with rebellion, harboured a large force of the enemy which constantly interfered with convoys from De Aar, so that in March W. Doran and Younghusband had to act together to clear the road. In the vicinity of Richmond Road Station, Berwick-Copley and Wormald were engaged keeping Commandos at a distance. In fact the Columns north of the Cape Town railway were mainly occupied in looking after the long wire fence, not inaptly compared to the Great Wall of China. \*

\* The "Times History," vol. v., p. 512, speaks very lightly of the value of this line. It says, "We may briefly remind the reader that the great length of this line, the remoteness of the country it traversed, and the fact that it only touched a railway at one end rendered it of little value, while its construction, necessitating several covering columns, and a large part of the already inadequate transport, caused much embarrassment to the active operations which it was meant eventually to assist. Not completely finished by May, 1902, it was never efficacious either as a barrier or as a line of supply."

*THE VETERINARY HISTORY OF THE  
VICTORIA WEST BLOCKHOUSE LINE.*

The construction of the blockhouse line gave rise to important veterinary conditions. Donkey transport is used in the Karoo, for as we have seen, no grazing exists for cattle, while the donkey lives on the bush. In order to press on with the construction of the line, the urgency of which may be gathered from the previous account of the military operations, ox transport was introduced, and from that moment trouble began. The cattle came by rail from the Eastern Provinces of Cape Colony, from a part not affected with cattle plague, and were railed to Victoria Road, which to them was practically a desert. Cattle plague was still rife around and north of Kimberley, and in the vicinity of Aliwal North, so that special provision was made at Victoria Road for dealing with an outbreak of disease.

One thing perfectly clear was that if the animals carried to Victoria Road were free from plague, it was certain they could not contract it at that place, or on the blockhouse line to Carnarvon, as no other cattle existed in the country. This essential fact seems to have been overlooked by the Veterinary Staff on the spot, though it was the key to the position; its nervous apprehension was the cause of untold trouble to the Senior Veterinary Officer of the Colony, 400 miles away, and of anxiety to the military authorities. As an example of administrative difficulty, an outline of the story will be related.

From Victoria West to Carnarvon is 70 miles, and by January this section of the line was completed. Carnarvon now became blockhouse-head for the construction of the section to Williston. This work began in February, there being 3000 oxen employed, and at blockhouse head a lay Inspector of Cattle was posted. The man had considerable experience of cattle plague. On 10th March he reported the existence of the disease at Carnarvon in a "mild form," and in his telegram undertook to "soon stamp out with serum." The man had blundered, but his report proved alarming to the military authorities, for come what might, the line had to be constructed. The scare created by this baseless story never really subsided, a feeling of insecurity was established, and this was subsequently intensified by the errors of the local Veterinary Staff.

The real cause of the mortality on the Carnarvon section was starvation. This was equally evident among the animals at the Victoria Road end. Early in March 7500 cattle were being employed, and with an increase in numbers there was an increase in mortality. On 15th March the deaths were declared by a Civil Veterinary Surgeon to be due to cattle plague, and once more there was an outbreak of official anxiety, cries for serum, orders and counter-orders by irresponsible Transport Officers, and others. It was with difficulty among all the tumult, and the interference by incompetent

and unauthorised people, that the Senior Veterinary Officer, the sole responsible man, could make his voice heard. He made the positive statement, based on an inspection of the cattle and post-mortem examination of fatal cases, that the disease did not exist, and that the deaths were due to "redwater" and starvation. By 25th March there were no less than 10,000 oxen employed on the line, and how they existed is a mystery, for of grazing there was practically none; the question of a daily ration had long been pressed on the military authorities, but it was not until the 7th April that one was sanctioned, consisting of 10lb. hay and 5lb. mealie meal per head. Day by day the cattle were getting weaker; at one time they could do the journey to Carnarvon in four days, they now required nine. A third rinderpest scare at this time did not help matters. The transport authorities ordered the inoculation of cattle which were dying daily from other causes, and so wasted some thousands of doses of the invaluable serum which had taken three months to prepare. This was a grievous loss at such a critical time, with rinderpest to the North and East. Still worse was the risk of contaminated bile, which was being sent in by the Transport Department from infected areas, and used without reference to the S.V.O. No better measures could have been devised, short of sending infected cattle, for introducing the disease into what was still a clean area. Considering the extraordinary military urgency of the situation, it is not perhaps to be wondered at that the authorities adopted this ignorant measure, for which the Veterinary Staff on the spot must be held responsible; nevertheless, it is by no means clear why the responsible military veterinary adviser in the Colony was not consulted before adopting a course so full of danger. He practically stood alone in his attitude towards the disease, and in opposition to the steps taken by the Transport Service; he showed that starvation, and not cattle plague, was killing the animals, and the Civil Veterinary Department of the Cape, whose interests in this matter were enormous, were able by independent inspection of the affected to support this view. When cattle plague began to be discredited, the local veterinary staff fell back upon anthrax as the cause of the mortality; it was little short of extraordinary that every cause but the real one of starvation was being searched for. It must be remembered, however, that with one exception, the veterinary staff at Victoria Road had no experience of rinderpest, and were naturally nervous and anxious at the heavy mortality occurring, which still continued, for the food sanctioned on the 7th April came too late to be of much use. Making every allowance for its want of experience, there was also evidence of a strong inclination to stick to a mistake.

It is interesting to place on record that the experimental evidence finally relied upon by the Victoria Road staff as proof of the existence of rinderpest, was based on the inoculation of a calf,

which, at 48 hours, showed a rise in temperature and diarrhoea. Without waiting for something more definite, cattle plague on this evidence was reported to exist, though the calf was well in a day or two, and so remained. *Sparrows* also had been inoculated, and as all died in less than forty-eight hours (from being shut up in a cage), there seemed to be no doubt in the mind of the experimenter of the correctness of his conclusions! It is remarkable that any mind could have harboured such absurdities, and regarded the above observations as proof of the existence of pestilence. Perhaps one ought not, under the circumstances, to wonder at the attitude of the military authorities. These facts are mentioned as evidence of the difficulties on service of always having the right men on the spot. It frequently happens that by accident the gravest responsibility falls on the weakest vessels, and that the reputation of a whole department may depend on their action or advice.

The debility farm of the Victoria Road depot was a few miles away, and contained 1400 cattle in all stages of decay and neglect. It was wet weather, and the worst cases after a cold night were unable to rise. They were quite free from any signs of rinderpest, but there was ample evidence for the necessity of some improvement in their management. The dead were receiving superficial burial by the dam which furnished the only source of water supply; the forage was unprotected, and among the bales the debilitated cattle crawled in for their last meal, and several lay there dying. The hay was soiled by their excreta, and for some distance around this mound of forage the ground consisted of mud and trampled-in hay, after the latter had been brought immense distances and at vast expense. The food, sanctioned too late to the working oxen, had of necessity to be thrown on the ground as there were no feeding places. Hay and meal alike were swallowed up in the mud, or blown away with the dust. Before the end of May the deaths in one week amounted to over 1200. The ox transport was destroyed; on 14th May steam had to take its place, and donkeys were now employed. By July the few cattle survivors were railed south; in a seven hours' journey 15 died in the train, and the balance was thereupon detained as "suspected." Once more the veterinary staff called in pronounced the disease to be rinderpest, but the war was over, and only the civil authorities were now anxious, and their veterinary staff fortunately had full knowledge of the previous facts of the case. The blunders over these cattle were extraordinary, and those committed by the veterinary service ought never to have occurred. We may conclude the story by saying that practically none of the animals survived. When the railway was found too rough for these poor starved remnants, an attempt was made to march the remainder away at their own pace, but they died on the road, and a mere handful reached their destination.

It seems hardly necessary to point out the lessons which the above teaches. The same blunders

in employing the wrong class of transport animal might occur to-morrow; the same folly of trying to get the animals to live without food; but never again, let us hope, will the same veterinary ineptitude be exhibited.

In the north-east of Cape Colony Fouché was still supreme. Follett had advanced from Dordrecht against him and P. Wessels at the end of December, but without result. Monro and Lovat, combined with Follett in January, and on 11th made another attempt: contact was established with Fouché, who, after inflicting many casualties on 17th Lancers escaped. Meanwhile L. Wessels went south-west, crossed the line, followed by Price with the Kaffrarian Rifles, and got into the stronghold of the Bamboos Berg. Fouché now being isolated, five columns "drove" for him but he disappeared. L. Wessels in the Bamboos Berg was hunted by Price, but managed to escape, recrossed the blockhouse line and rejoined Fouché. On 17th February the two were in the vicinity of Jamestown. From here both Commandants again entered the midlands, crossing the blockhouse line on 28th February, and Price and Monro's mounted troops under Baillie went in pursuit. The chase lasted nearly three weeks. Price, who knew the country, was rarely off Fouché's heels and attacked him whenever possible. Fouché's Commando broke up under pressure, one half led by himself went south and was followed by Price, the other, under Bezuidenhout, was followed by Baillie. Fouché, in his southerly run, reached Jansenville on 16th March, bounded west across the Graaf Reinet line, and then made north for the Camdeboo as hard as he could go with Price on his heels. He finally gained the security of the mountains south-west of Graaf Reinet after a chase of not less than 260 miles. In the Camdeboo he met Malan.

Baillie fared no better with Bezuidenhout, who, in his journey, described a circle of about 180 miles in circumference, which brought him back to the Bamboos Berg quite close to where he started. On 2nd April he crossed the line east and made for the Jamestown District followed by Moore and Lovat. Hunted here by Lovat, he was, by the end of April, owing to the loss of men and equipment, reduced to impotence, though never captured.

#### CAPE COLONY.

##### THE LAST CHASE OF THE WAR.

MARCH TO MAY, 1902.

By 26th March, B. Doran having refitted, combined with Price in a sweep of the Camdeboo Mountains in quest of Fouché and Malan. The enemy was driven from position to position, and finally by the end of the month ousted in small parties to the west into the Murraysburg district. Two sweeps of this district by four columns took place in April, including the Camdeboo Mountains, but without result.

Fouché and Malan represented a combination of extraordinary difficulty, such as might have been anticipated from the previous history of the chase after them. They were both specially marked for capture or destruction, and it will be of interest, as evidence of the work this class of operation imposed upon the horses, to know the measures which were taken in the last days of the war to endeavour to effect this.

It began by another series of sweeps over the Camdeboo Mountains. To and fro from Nelspoort to New Bethesda was this mountain range swept in May by Baillie and Doran, but still with negative results.

B. Doran was now joined by a fresh column under Bewicke-Copley, and other troops were brought in to assist, but before the reinforcements arrived Malan and Fouché left the Camdeboo Mountains and went south for Aberdeen, which they unsuccessfully attacked on 18th May. Now began a chase as remarkable for the endurance, courage and determination of the fugitives, as for the extraordinary efforts put forth to effect their capture.

Imagine an irregularly semi-circular course, 240 miles in length, over mountains and sandy plains, intersected by two lines of rail, and heavily block-housed near the winning post, the latter being the ground north of the Bamboos Berg.

Following the fugitive band are the columns of Lovat, Bewicke-Copley, B. Doran and W. Doran, sometimes in hot pursuit, at others cutting off corners to intercept, while bodies of mobile and local troops are stationed here and there, as the scene shifts, to intercept or prevent breaking back or breaking out from the enormously strong position which has been prepared to receive them. This latter is the objective, and to it they have to be driven. At first they go south, but gradually are moved in a large semi-circle until their heads are pointing in the required direction, north-east. On 20th Lovat reaches them, and has a fight which costs them 100 horses, but away go the Commandos with a column on each flank to contain them, another behind to keep them on the move, a fourth on the line of rail ready to steam to a distant point and intercept. The time for the latter arrives on the 27th, B. Doran being sent ahead by train. He reaches a point on the line of rail for which the fugitives are rapidly making. The crossing being denied them, the Commandos try to break back through Lovat; the latter closes, and in the encounter Malan is severely wounded and captured, while the remnant of the band streams away north in spite of the presence of B. Doran and an armoured train patrolling the track. The harrassed Commandos cross the line on 28th May, and speed through Bedford, cross the Winterberg Mountains, and approach Taarkastad, but are blocked by Lukin, while a break out to the east is provided against by troops on the East London line.

The end is approaching, for the Commandos are near to the Bamboos Berg through which it is intended to drive them on to the railway, now con-

sisting of an impenetrable wall of blockhouses. To prevent a possible break out to the west, the 2nd Dragoons are waiting at Maraisburg; should they get through this, another mobile body lies behind them, and exclusive of these a further blockhoused line lined for 100 miles by troops. The position for the fugitives is hopeless; the Bamboos Berg are now in sight and the end at hand, but with it came June 1st. The war was over.

The number of columns which took part in the operations in Cape Colony, January to May, was twenty, consisting of 11,000 horses. The casualties were very heavy, and hospitals were established at Clanwilliam, Sutherland, Piquetberg Road, Magersfontein, Carnarvon and Victoria Road, in addition to those previously existing, including the large debility establishment at Worcester, into which the cases were poured by tens of hundreds. As giving some notion of the amount of sickness, there were over 2000 sick animals at Worcester, of which 1500 were suffering from scabies and debility. We may say that at the lowest estimate the operations recorded above resulted in a loss of 2700 animals per month, of which 600 died or were destroyed.

#### THE NAMAQUALAND OPERATIONS.

JANUARY-MAY, 1902.

It will be remembered that the scheme of Smuts not only included an attack on the advanced bases being held in the wired-in districts to the north of the Cape Town line, but also a descent on the north-west territory of the Cape. This introduces us to the far away inhospitable regions of Namaqualand and Kenhart, to which a force under Maritz had been despatched. Ookiep, the capital of Namaqualand, was a place of importance owing to the copper mining industry, and was connected with the sea at Port Nolloth by means of a line of rail thirty miles long which ran through an absolute desert. Ookiep was of value to the enemy owing to the immense capital its mines represented. To reach it was a long journey for him, but all through a friendly country, for nowhere more than in these wild desolate sparsely populated northern regions was the hatred of everything British more firmly rooted.

This feeling had been shown early in the war, pp. 61 and 164. Though measures had then been taken to deal from the east with the territory as far as Upington, it was not possible until August, 1901, to form a mobile column for the purpose of maintaining order. This column was under Col. White, and what it accomplished in the way of marches in the desert area contained within the vast triangle, Ookiep-Upington-Van Rhyn's Dorp, has never been described. His opponents were all rebels more bent on thieving than fighting. In January, 1902, White was at Kenhart, where he had been engaged with the enemy. Hearing of the mission of Maritz, he hurried across to stand between him and Ookiep, but Maritz got behind him, and White, now at

Garies, unable to move to Ookiep, would have fallen into the hands of Maritz but for the services of a small regular and local force which had placed Garies in a state of defence. The subsequent attack on and defence of Ookiep does not concern us, but its relief was effected from Cape Town, troops being sent by sea to Port Nolloth and railed across the desert. The town was invested by the enemy on 31st March, 1902, by which time Smuts had arrived. It was relieved by Colonel Cooper on 4th May, the mounted troops with him being under Callwell.\*

White at Garies was relieved by Kavanagh's column from Calvinia; Wyndham's column was established at Van Rhyn's Dorp, while Smuts proceeded to Vereeniging to discuss terms of peace.

#### EASTERN TRANSVAAL.

##### BOSCHMAN'S KOP.

OPERATIONS: APRIL, 1902.

The area to the east of Pretoria, described at p.168 as protected, was the scene of military operations during April. The term "protected" had become a misnomer, for since the previous January it had been the home of a Commando under P. Viljoen (see p.183), and in February, during one of the Free State drives, General Alberts from the Free State with 500 men had joined him. All endeavours to oust these Commandos from the protected area had been uniformly unsuccessful. In December, 1901, Gilbert Hamilton with a Cavalry Brigade suffered reverses, and again in February it was roughly handled. Since then these Commandos had moved about the protected area enjoying complete immunity. Though in strength about 1200, this district for many weeks was able to provide subsistence for this number of horses and men, yet a single British squadron would, under like conditions, have starved in a week. As the "Times History" says, how these people lived was a mystery. "The country was a wilderness; not a beast, not a field of standing corn, not a native was left. Some trampled mealie fields offering a niggardly harvest to very careful gleaners were the only signs of sustenance."† There must have been hidden supplies of food available for both horse and man.

On 2nd April another attempt was made to deal with these Commandos. Lawley, who had taken the place of G. Hamilton, brought with him from the Free State the 7th Hussars and 2nd Dragoon Guards. On 31st March he was at *Boschmans Kop*, 18 miles south-east of Springs. The following morning before daylight he sent out the 2nd Dragoon Guards, 300 horses strong, to surprise a piquet of the enemy, 12 miles east. It was a dark wet morning; the regiment walked into the arms

of a Commando 800 strong, which was as much surprised as they. The Commando soon rallied, and adopting their modern tactics charged boldly up to the squadrons at point blank range, also endeavouring to cut them off from their base. The last seven miles to camp was across a level plain where no defensive position could be found, so it resolved itself into a neck and neck race. As they neared their camp the Artillery opened fire, the 7th Hussars came out and the enemy then withdrew. The losses were over 80 horses and men, and at one time the whole regiment was in peril.

It was evident that in spite of the harrowing to which this State had been subjected, the spirit of resistance was still there, and another drive across the Eastern Transvaal was inaugurated by Bruce Hamilton, whose seven Columns, totalling 7000 mounted men, were drawn up in a line from Great Oliphants Station to Carolina, points 60 miles apart. From here on 12th April they "drove" south to the Standerton line which was reached on 14th, the distance apart of the two lines is 80 miles, so that 40-mile marches were made. The enemy met these columns by "charging" tactics, so that men literally smashed a way through the solid rank, with very little loss excepting in prisoners.\*

When B. Hamilton arrived at the Standerton line he was joined by four columns which had just left Elliot's big drive in the Orange Free State, p.214. With eight columns he swept back on 17th April to the Delagoa line, thereby going from south to north, taking a course just west of his previous drive. But the fruits of this enormously expensive operation were three prisoners; the Commandos of P. Viljoen and Alberts escaped, the enemy having broken away to one flank and got clear. On the 23rd April a third of these cross sweeps was made, a little further west so as to touch Heidelberg on the Natal line, but only four prisoners resulted from this operation.

It is impossible for the civilian to realise what each "drive" meant to animals and men. "Each day, in rain or wind, or under tropical sun, they marched from dawn to dusk, each night they dug entrenchments, and strung up leagues of barbed wire entanglements before they lay down in the open, to the brief rest which many, from the necessity of finding innumerable outposts, never obtained at all."† If it was fatiguing to the men who rode, what must it have been to the horses who carried them? In all the above drives the piece of country to be swept was roughly 80 miles in length by thirty to fifty in width; so that it resolved itself into marches of forty miles a day for two days, then two or three days rest, followed by two more long marches.

At this time in the Eastern Transvaal there were 19 columns operating, of an aggregate strength of

\* The Veterinary Officer with Colonel Callwell was C. V. S. (now Captain) Greenfield.

† Vol. v., p. 562.

† "Official History," vol. iv., p. 521.

14,000 horses, and the wastage may be taken as follows:—There were nearly 3000 sick horses a month for the veterinary hospitals in that part of the colony, or to be drafted away to debility farms, and 700 horses a month either died or had to be destroyed.

#### ORANGE FREE STATE.

OPERATIONS: MAY, 1902.

##### THE LAST DRIVE.

When B. Hamilton had completed the work in the Eastern Transvaal just related, he crossed the Vaal into the Orange Free State, and in co-operation with Elliot a big sweep was organised. Before reaching the Vaal he drove from Greylingstad on 2nd May, on a line extending to Vereeniging, and continued it up to the northern blockhouse line of the north-east Free State, *i.e.*, Heilbron-Frankfort, which was reached on the 4th. The Eastern outlet lying between Villiersdorp and Frankfort, a space of 20 miles, was closed by Allenby. The results of the drive were that many of the fugitives broke through the blockhouse line, and some through Allenby's; but 90 were captured. In the next phase of this operation Elliot lined up from Lindley to Liebensberg's Vlei, and Barker filled in the space between Frankfort and Elliot's right. From the northern line of blockhouses B. Hamilton drove south on 5th May, his line of eight columns extending 60 miles in length, and consisting of 11,800 horses. The distance from his objective—the Kroonstad-Lindley blockhouse line—was 40 miles, and this was covered in two days. On 6th the enemy boldly charged Elliot's line, and burst through with the loss of only one man and twenty-five horses. A little later another party failed to get through and was captured, so that 300 prisoners were secured by the time the blockhouse line was reached.

The following day, 7th May, B. Hamilton turned about and drove north over the same ground. The driving line was here in parts prolonged to 80 miles, from the railway to the Wilge River. It may be visualised by thinking of the distance from London to Rugby. Two parties of the enemy broke back, and on the evening of the 9th the drive ended. With it terminated the last operations in the Free State, for on 10th, pending peace negotiations, all further offensive action was stayed.

It cannot fail to strike those who have had the patience to follow the two years of weary operations in the north-east Free State, the losses a small and determined enemy is capable of inflicting, provided they possess superior mobility. It would be interesting to know what our losses in animals were during that time! Fire, sword and pestilence are active and efficient methods of destruction, but for the general obliteration of animals, physical unfitness will compete with them.

#### WESTERN TRANSVAAL.

OPERATIONS: MARCH-MAY, 1902.

The serious turn taken by the events in the Western Transvaal recorded at p.213 led to a great concentration of troops at Klerksdorp, which now formed the base of all future operations. Grenfell, who was close to Lichtenburg, was recalled to Klerksdorp, and his column, together with that of Von Donop, was placed under Kekewich; it numbered 2800 horses. Rawlinson, who had followed De Wet and Steyn, p.211, was brought in from the Free State with his entire force of 2000 horses. W. Kitchener was given command of three columns brought in from the Eastern Transvaal, amounting to 3000 horses. Rochfort, with seven columns on the Vaal in the Bloemhof district, brought in 2500 horses. In this way 16,000 horses were concentrated and made up into four divisions, each 4000 strong. The sudden increase in the number of mounted troops in the Western Transvaal must be carefully noted. This area of the war had never been remarkable for either the number or size of its columns, and the veterinary requirements were met by outlying hospitals at Klerksdorp and Krugersdorp, which emptied their contents into the hospitals at Potchefstroom and Johannesburg. Suddenly Klerksdorp, with its small hospital, had become in a night the most important centre in the campaign, and would evidently be severely tried with so large a force based on that place.

The position of the enemy was unknown with exactitude, though large numbers were believed to be west of Klerksdorp. De la Rey had met De Wet about 25 miles west of Klerksdorp, and though the latter had returned after the interview to the Free State, Steyn remained behind, and was still with De la Rey in the position indicated. Kemp was 12 miles to De la Rey's west, and Liebenberg was once more back in the vicinity of Wolmaranstad, which had now been evacuated. A movement to the west was hopeful, and Lord Kitchener, who was personally present at Klerksdorp on 19th, gave orders for it to occur on the evening of 23rd March. The operations were remarkable for their simplicity, audacity, and severity on animals. Some 11,000 mounted men were to ride out for 40 miles west on a narrow front in three columns, and so get between the various Commandos. To enable this to be carried out, it had to take place in the dark, and to be done quickly. No less than 40 miles had to be covered in one night. The columns were then to open out, form one long line and drive back to the Schoon Spruit blockhouse line, which ran north from Klerksdorp. All these columns did not start from Klerksdorp. Kekewich moved off from Vaal Bank on the blockhouse line running from Lichtenburg to Schoon Spruit; Kitchener and Rawlinson from Klerksdorp, Rochfort from Commando Drift on the Vaal south of Wolmaranstad.

On the night of the 23rd, without guns or transport, the Columns passed out silently to the west, Rochfort to the north. The distance within the given time could only be accomplished by trotting. At dawn they turned about and opened out, forming a line 90 miles in length, or the distance between Birmingham and Cambridge. But there were gaps in this line; two Columns failed to get into touch, and Steyn, De la Rey and Kemp availed themselves of the opportunity and passed through. Liebenberg had more difficulty; in consequence he had to abandon the captured guns and waggons, but by going south escaped. Rain came down in torrents; the Columns, worn out by fatigue, reached their base 40 miles east by the evening of 24th March. The results were small, 1671 head of stock and 173 prisoners, and in consequence of the severity of the work the veterinary hospital was filled to overflowing.

#### ACTION AT BOSCHBULT.

The next movement decided upon by Lord Kitchener from Klerksdorp was to take place on 26th March. It was to differ in character from the last. Kekewich was to establish a fortified base at Middelbult, 23 miles south of Lichtenburg. W. Kitchener was to move to Driekuul south of Middelbult, and form an entrenched camp. Rawlinson was to march to Rhenoster Spruit, 16 miles west of Klerksdorp, while Rochfort remained on the Vaal. The troops were to operate from the position assigned to them, so transport and guns were taken. Kekewich was in position on 29th, and Kitchener on 30th March. At 2 a.m. on 31st Kitchener sent a Column of 1800 mounted men and guns under Cookson on a reconnaissance to the west of his position along the Brak Spruit. The horses carried two days supplies for man and horse, and mule transport carried a third day's supply. The force moved rapidly, and, without knowing it, in the exact direction of De la Rey's camp. At 10 a.m. a body of the enemy was sighted, and chased by nearly all the troops Cookson had, excepting those with the transport. At a hand gallop the enemy was followed for some miles, when suddenly a check occurred; they had been joined by re-inforcements, and now faced round on their pursuers. It was evident to Cookson that he must fight where he was; he had marched 35 miles since early morning, and any attempt at retirement would have meant annihilation. An eight-mile gallop brought him up some more men from the rear, and later on his transport arrived. Meanwhile he kept the enemy off while he entrenched himself. Generals like De la Rey do not usually give time for an enemy to improvise defences, but the fact was he had to call up Commandos, and it was not until 1.30 that he was in a position to make any serious attack. Meanwhile the laager, not yet completed for defence, had been formed in a farm on the edge of the Spruit, and the mules placed in the dry bed under cover. The attack at *Boschbult* was opened by Artillery fire, the explosion of the shells in the laager stamped

some of the still inspanned mules, which broke away and created confusion in a Company of Mounted Infantry. Advantage was taken of this by the enemy to charge the laager, a line four miles long advancing for this purpose, but they were received by so severe a fire that they moved away. By the early afternoon the defences of the laager were sufficiently advanced to allow of a screen hitherto in the open to return to cover. Its retirement was the signal for a fresh attack.

Fighting continued until the evening when the enemy retired. It was De la Rey's last fight. All night long Cookson was strengthening his defences, for which purpose the bodies of his slain animals were largely used. The casualties were heavy, 364 horses and mules had been killed in the laager, and 100 men killed and wounded. Next day Cookson could not have moved had he so desired owing to the destruction of his transport animals; by mid-day W. Kitchener arrived, and both Columns returned to Driekuul on 2nd April.

The remaining operations in the Western Transvaal were conducted by General Sir Ian Hamilton, who arrived at Middelbult on 8th April.

#### IAN HAMILTON'S OPERATIONS.

APRIL AND MAY, 1902.

##### ROOIWAL.

Hamilton feeling certain his enemy was to the south in the vicinity of the Brak Spruit moved in three columns on 10th April. Kekewich being on the right, Rawlinson in the centre, and W. Kitchener on the left. By night the right was at *Rooiwal*, almost on the ground where Cookson met De la Rey at Boschbult, and not far from the scene of Methuen's disaster. On the morning of the 11th a strong force was seen bearing down on Kekewich, which, from its regularity, was believed to be one of the other columns, nor was it until the enemy was quite close and already among the advance screen that all doubts were at rest. Von Donop and Grenfell, the two lieutenants of Kekewich, rapidly formed an irregular line; they had but a few seconds in which to do it. The enemy was advancing towards them at a slow canter in line two and three deep, firing from the saddle and shouting. They were met by a rattle of musketry and case from the guns, but it had no effect. Riding at their head was Commandant Potgieter; nearer and nearer approached the intrepid horsemen, facing a stream of fire which, though it thinned their ranks, did not diminish the astounding courage which animated the best soldiers of the Federal armies. These men had been trained under a master in the art of war; he, De la Rey, was absent discussing terms of peace, and Kemp was in command. Without increasing or diminishing the pace, the enemy advanced nearer and nearer, until but 100 yards separated them from the line of magazine fire; then they turned, though not their leader; Potgieter was killed 70 yards from the line. The mass retired

at a faster pace than it advanced, and one of the most wonderful sights witnessed in the war was over in a few minutes.

In describing it, the "Official History" \* says:—

"The howling rush of the Dervish or Ghazi, the sonorous charge of European Cavalry, the chanting onset of the Zulu impi, were less impressive than the slow oncoming of this brigade of mounted riflemen." \*

There was no Cavalry on the field to pursue: Grenfell had 150 horses killed, exclusive of those in the advance screen, and many had stampeded. It was an hour before any steps could be taken to follow up the demoralized enemy, and by that time Hamilton had arrived. Pushing on with 2000 mounted men in a southerly direction he soon came in contact with Kemp, who had not expected pursuit, and for three hours this was kept up until 18 miles had been covered, and the horses could go no further. The force then returned to Rooiwal after being in action 14 hours. The losses among the horses during the attack amounted to 300 killed; these casualties occurred wholly in the columns of Kekewich.

There is a lesson in this which applies to all hastily constructed machines in war. According to the recognised rules of war, the enemy under the effect of magazine fire should have been swept away. As a matter of fact their losses were relatively small. Our men could not shoot straight. The "Times History," vol. v., p. 529, in speaking of the composition of Hamilton's force, says:—"There were hundreds of townsmen among the Yeomanry who had barely been able to sit a horse or sight a rifle when they first came to South Africa. No Mounted Corps on the field had had a separate existence before the war broke out, and only one, the Imperial Light Horse, was as old even as the outbreak of war."

The principle which applies to this fine body of imperfectly trained men, equally applies to all branches, be they combatant or non-combatant, when the country has to depend upon the willing but untrained services of the general public. So far as the veterinary service is concerned, we have in these pages made this abundantly clear, but it is well to see its effects in the combatant ranks, in order to relieve our criticism of the risk of being considered ungracious.

The final operation in the Western Transvaal remains to be told. The "drive" was still the only military weapon of any value, and we have watched its effects upon the horses during the process of its evolution. The two latest applications of this measure were represented by a long line advancing many miles daily and closing up gaps at night, or by columns shooting out rapidly for 40 miles into the veldt on a narrow front, turning about, deploying into one long continuous line and driving home for 40 miles at their best pace. There is, of course, no question which of these is the most costly in

horses; experience showed that there was practically no difference in the tactical results obtained.

Hamilton adopted a sound measure from a horse point of view in the last drive of the war. He had been strengthened by the addition of two divisions, that of Thorneycroft with his two columns of Australians and New Zealanders, and Rochfort's column which had been operating on the Vaal. His force was now brought up to 17,000 horses, the largest mounted body ever placed in the hands of a British General. He was in the middle of the southern half of the Western Transvaal, and from this point he intended to drive towards the west on to the blockhoused Vryburg-Mafeking line. His troops were arranged in one long line extending for 30 miles, in a position which may be roughly indicated by saying that it occupied the whole middle third of the space between Lichtenburg and Wolmaranstad. This bush-whacking of a continent required a great deal of thinking out, as both ends of the line were in the air and therefore vulnerable. This was guarded against on the south by Rochfort coming up from the Vaal and joining the advancing line the day before the blow was to fall. When he came into position the line was 50 miles in length, equivalent to a line of horsemen extending from London to Basingstoke. The driving distance from where Hamilton started to the Vryburg railway was 80 miles. Five days were to be occupied, so that the average day's march was 16 miles, which left the animals fit at the end of it, in spite of the inhospitable nature of the country generally, and its waterless character.

The account of these operations given by the "Times History," vol. v., cannot be omitted. In referring to the net now approaching the Vryburg blockhouse line it says:—

"Behind the 300 in the cordon were 17,000 troops entrenched. Thorneycroft dug redoubts at every 100 yards for six miles, and filled in the interval with waggons and barbed wire. Kitchener's redoubts were 50 yards apart. In front of the 300 were six armoured trains and 45 miles of blockhouses manned by 4000 rifles. It was the night of the 10th May, the day before the armistice."

The drive concluded on 11th May, and resulted in the capture of 367 prisoners. On 17th, the columns returned to their several bases and awaited the result of the peace negotiations.

The war was over.

In the 29 columns existing at this time in the Western Transvaal there were 20,700 horses; the work done by 17,000 of these we have just related. We must now look at the question of the veterinary arrangements made at Klerksdorp for the care of not less than 3000 sick, resulting from the last month's operations.

\* Vol. iv., p. 501.

# VETERINARY HOSPITALS DURING 1902.

The pressure exercised on the veterinary hospitals during 1902 was greater than ever, owing to the existence of specific lymphangitis in addition to the other epizootics. The general sick rate had been reduced in consequence of a change in the character of the work, and the greater care and attention paid to animals resulting from Colonel Long's inspection of columns. For example, just prior to his appointment there were 27,900 sick for the week ending 24th October. Four months later the total sick amounted to 17,700. It is true it again rose on the 14th May, and stood at 24,700 sick, but there had been a great increase in the number of horses employed.

The work of the hospitals generally had improved, the great difficulty was to obtain sufficient native labour, and this became so acute in connection with the Klerksdorp Hospital during the period of the Western Transvaal Campaign that men had to be sent from other hospitals in order to try to cope with the pressure, and finally white refugees had to be employed.\* Most of the hospitals were working smoothly. The exception was in the Eastern and Western Transvaal where the congestion was intense. Nevertheless, the general efficiency was satisfactory, as an example of which the returns for the week ending the 14th May may be quoted. During that week 6000 horses were discharged from hospital to duty, an average of 120 weekly from each of the fifty hospitals. The discharge of this large number afforded no relief to the work, for 7000 others were admitted to treatment.

The chief interest in hospital work during the last month of the war centres around the small branch hospital at Klerksdorp, which had suddenly to expand to meet military requirements. It could not expand fast enough owing to the deficiency of labour and the poverty of the water supply. No water was laid on, and the shelters for the sick were few. The hospital also worked under other difficulties; from one cause or another those in charge of it were frequently changed. There was a change on 27th November, 1901, another on 24th January, 1902, 8th February, and again on 18th March. It must be remembered in this connection that at this time two officers were controlling the energies of the Veterinary Department, Colonels Matthews and Long. The former was endeavouring to meet the urgent demands made on him by Column Commanders for veterinary aid, the latter was opposed to the supply, and wished the veterinary staff to be withdrawn from columns and placed on the line. Extra Field Hospitals had been ordered by the Authorities which had to be staffed and to which Colonel Long objected, not knowing at the time that it was the Commander-in-Chief's order;

\* The experiment of employing 150 convalescent soldiers at Pretoria for hospital duties, in order to liberate natives for the Klerksdorp Hospital, was a hopeless failure. Not only were the men unfit for hard work for reasons of health, but they could not handle mobs of horses.

equally, and for the same reason, he took exception to veterinary officers being sent to columns. A dual control necessarily always creates an impossible position; nevertheless, the frequent changes in connection with the Klerksdorp Hospital ought, in principle, to have been avoided, for such changes are fatal to effective working. The P.V.O. was anxious to have a senior officer of the A.V.D. in charge, and this he was unable to effect until 18th March.

The officer selected had only been a few days in Africa, knew nothing of local conditions and difficulties, and had barely taken over when his assistant officer was found unfit for service and sent on sick leave. The sick in hospital on 18th March amounted to 550, and was daily rising. Stabling, water supply and labour had been promised, but were not forthcoming sufficiently fast to meet the urgency of the situation. The P.V.O. had personally been present at Klerksdorp to push matters along, and he was followed a little later by Colonel Long. But even the latter—who, of course, owing to his official position was responsible—could make no headway; buildings, water, and mangers take time to construct; nose-bags and line gear could not be obtained in sufficient quantities to meet the daily increase in the numbers, and to obtain labour locally was impossible. On 25th March there were 1000 sick with personnel for half the number. Already a hospital for 1700 sick had been projected, but until it could take shape† it was evident that the sick must be sent away from the place, a scheme which the Authorities objected to owing to the congestion of all the other hospitals in the district. Potchefstroom, for instance, already had 1400 sick of its own, Johannesburg 2300 sick, Krugersdorp was full to overflowing, and to further increase the personnel difficulties a fifth hospital was ordered to be formed at Springs, near Johannesburg, for 500 animals. In the first days of April the P.V.O. was again at Klerksdorp. An Australian and New Zealand contingent had arrived, 2500 strong, and 90% of their horses had been affected with influenza, and 25% were still suffering. It was impossible to find accommodation for these, as the number in hospital at Klerksdorp on 9th April stood at 1200, so they had to form a depot for their sick in which 300 animals were placed.

We have seen from the dates of operations the number of times columns returned to Klerksdorp for re-fitting, and always adding to the sick. On one day in March, 360 horses out of a total of 700 with Kekewich had to be sent to hospital as being unfit for work, and such examples were numerous.† The pressure of work on the black labour employed in the Hospital rose to breaking point, it was impossible to get the horses properly watered or

\* Stabling for 500 sick was not approved until 20th April.

† In his evidence before the Royal Commission, Major-General Kekewich stated, Q. 22,024, that during the last month of the war he used up 1500 horses. His strength at the time was 4000, so that his loss was 37·5% a month, or 450% a year.

fed, and the extra labour sent from time to time never met the urgency, as the sick list rose by leaps and bounds. On 20th April it stood at 2200, and a day or two later approval was given to reduce the strain by sending 500 of the sick to other hospitals. It was not, indeed, until the urgency had passed away that proper accommodation for the sick, water supply, and labour were obtainable at Klerksdorp. In the meantime another hospital break-down had been placed to the credit of the Veterinary Service.

It was not as if the grinding machinery had stopped working elsewhere, which would have enabled further aid being sent to Klerksdorp. The account given of the operations will show how far that was from being the case. In fact, the congestion of the hospitals on the line from Johannesburg to Natal in the Eastern Transvaal, was as bad as it was in the Western Transvaal. The hospital at Standerton had been receiving the sick from Bruce Hamilton's operations, and on 29th April there were 2300 cases in hospital, more coming in, and labour urgently required. One hospital further down the line had to be closed owing to the failure of water supply, and its sick distributed to places already congested.

Returning to Klerksdorp, from the 24th April the work had to be carried on single handed owing to the sickness of the second officer, and we may briefly look at the duties which had to be performed by the one who was left. In hospital he had over 2000 sick. Every column based on Klerksdorp had a debility depot of its own, of cases requiring rest. These depots had to be visited daily, and the cases of glanders and mange they contained weeded out. There was a large transport depot with sick animals, a depot for captured stock, the cattle in which were suffering from pleuro-pneumonia, "red water" and rinderpest. Both of these had to be visited and assisted. Finally the hospital had to take on the duties of the supply of veterinary stores to units in the Field, a laborious and time-consuming service. Under the above circumstances there appears to us to be good excuse for the failure of Klerksdorp as constituted to meet the requirements of sudden and intense military activity. Yet we shall ever deplore the dual control in administration, and regret that the undivided attention of a senior administrative officer with long experience of the war was not devoted to this one centre of extraordinary activity, with three or four officers placed in the hospital for executive duties. These steps could not have affected the water supply, nor the shortage of nose-bags, the absence of mangers and stabling, and the poverty of black labour; they would not have prevented the hospital being crushed under the pressure exercised upon it, but they would have prevented any reproach on departmental arrangements.

On the day peace was proclaimed there were 28,700 sick horses and mules in South Africa, of these 19,500 were in the fifty existing hospitals, the

balance being on debility farms under Remount management.

On the same day the Veterinary Service with Units, Remounts and Hospitals consisted of:—

Veterinary Officers	63
Civil Veterinary Surgeons	113
European Dressers	79
Indian	528
Civil Farriers, Conductors and Clerks	217
South African Natives	3547

We are fortunate in having recently had placed before us the cost of the upkeep of a hospital in South Africa.\* One for 1500 animals at Middelburg cost £245 a day, of which £187 was for rations for the horses. As the animals would have to be fed, whether in or out of hospital, it is thought the charge for rations should not be placed against the cost of maintaining a hospital, in which case the expenditure would be reduced to £58 a day for 1500 sick. The astonishing fact comes out in Major Cochrane's paper that the cost of drugs and dressings only amounts to one-fifth of a penny per day per horse, or 4s. 2d. daily for 1500 animals. These figures are the outcome of direct observation and painstaking inquiry; it will be impossible in future to argue that it is cheaper in war to allow horses to die than to institute a place for their medical and surgical treatment; even if the other condition (acclimatisation) urged at pp.134-135 was not permitted to carry weight.

The declaration of peace brought no reduction in the numbers in hospital, on the other hand they increased, for animals which could not previously be laid up for treatment had now to be admitted. The number of hospitals were now gradually reduced, for a large hospital run on good lines gives far better results than several smaller hospitals of unequal value. Nevertheless it was ten months after the war before the hospitals fell to nine, the number then fixed as the future establishment for the country.

#### *THE REMOUNT DEPARTMENT IN 1902.*

By 1902 a system had been in operation which could not now be changed, we allude to that of placing animals in the ranks as soon as they were landed. It is true an effort was made to avoid this, but under military pressure all regulations in this respect had to be swept aside for the time being. It was these spasmodic outbursts of activity which proved so wasteful of horses.

An Inspector-General of Remounts for South Africa, whose appointment was notified in Cable No. 101, see p.189, arrived in South Africa on 31st Dec., 1901, and took over the duties by inspecting

\* "Veterinary Hospitals during War," Major R. C. Cochrane, A.V.C.—*United Service Magazine*, Nov., 1913. This paper ought to be read by all interested in the question of hospitals, including economists.

the various Remount Depots in the Command. At this time, therefore, there existed an Inspector-General of Remounts with a Staff Officer, together with a Veterinary officer, Captain Carr, A.V.D., who acted as ungazetted A.D.C. to the General. In addition, there was an Inspector of Remounts and Hospitals, and an Assistant-Inspector of Remounts. The result of the inspection by the Inspector-General of Remounts of the various Remount Depots in the Cape was, on the whole, satisfactory.\* The depot at Durban he condemned, as in wet weather the horses stood up to their hocks in mud. The climate also was bad for horses, and the animals lost condition. A rest camp had accordingly been formed six miles from Durban, and from here the horses were forwarded to a large farm twelve miles north, where accommodation for 2000 was in course of time erected. The Inspector-General considered the Natal Remount work was "much worse organised than the others," but, with a change in administration, improvement was hoped for. He observed that mangers did not exist in all the depots, but had been ordered, and that water was not always laid on.

The remount depots were divided by him into three groups: landing depots at Cape Town (Stellenbosch), Port Elizabeth, East London, and Durban; issuing depots at De Aar, Bowker's Park (Queens-town), Bloemfontein, Johannesburg, Standerton and Newcastle. Resuscitating depots (debility farms), at Worcester, Naauwpoort, Craddock, Stormberg, Aliwal North, Burghersdorp, and Dordrecht in Cape Colony, Lynch's Farm at Bloemfontein, Heilbron, Winburg, and Springfontein in the Free State. In this report the condition of the defective depot at Mooi River is not specifically referred to.

The Inspector-General drew attention to the fact that the Remount Officers employed in the various depots all over South Africa had no previous experience of remount work, but were doing their best.

Regarding the length of time given to horses after landing in order to fit them for work, a point into which he was specially charged by the War Office to enquire, he says: "Lord Kitchener told me he had given orders that no horse was to be issued for use with columns on service until it had been a month in South Africa. Very few of the officers I found knew of this order, and horses were continually sent to depots up country with no description of them or date of their arrival in the country. I gave stringent orders to remedy this, and called in all horses I found already issued that had been too short a time in South Africa."

The Inspector-General of Remounts did not remain long in South Africa; by the end of March, 1902, he was in Australia, and the only matter of professional interest connected with his report from that country, is a note on the needlessly large veterinary staff maintained there. His remarks on

this matter must be reproduced, as they have a bearing on a very important question. "Civil Veterinary Surgeon Conacher was sent from Pretoria to see whether blue (*sic*) glanders existed in Australia. Now, as there were in the country two very competent men, Veterinary-Captain Nuthall, A.V.D., and C.V.S. Taylor, the sending of Mr. Conacher appears to have been but a useless expense, especially as I know that competent veterinary surgeons were terribly wanted at the time in South Africa."

As to the nature of "blue" glanders we know nothing, and never heard of it until it appeared in this report. It is most unlikely that Colonel Matthews would send anyone to Australia to look for a disease which did not exist, and the question arises as to who sent this gentleman looking for glanders in a country where it has never been seen? Mr. Conacher was attached to the Remount Department, and his visit to Australia, so rightly condemned by the Inspector-General of Remounts, may have been connected with the evidence given by Col. Darby before the C. of E. Remounts dealt with at p. 203.

Returning to a general account of the remount operations during 1902, there was probably no period in the war, since Bloemfontein in 1900, when the pressure had been so great as from March to May, 1902. An increase in the number of horses sent to the country was met by an increase in the size of the depots. We have already seen that this occurred in Natal, but, in addition, the Port Elizabeth depot in January was nearly doubled in size.

One of the very busy remount centres during 1902 was the improvised depot located at Klerk dorp. Prior to the Western Transvaal Campaign it was merely a place where columns threw in their sick and worn, and received fresh animals in their place; but the operations undertaken in March, April and May necessitated a rapid and considerable expansion, such as had never been anticipated. The depot, in fact, suffered from acute congestion, for the same reason as we have seen the hospital did. Standerton was another extremely busy centre, the Natal Railway being actively occupied during 1902 in pouring up remounts to Johannesburg. With a change in the local administration at Mooi River, a marked improvement occurred in a large and important depot which had become a reproach, see p. 201.

The inspection of Remount Depots by Colonel Long and the Inspector-General of Remounts had led to considerable structural improvements, while their veterinary supervision throughout South Africa having been in the hands of Major Blenkinsop, D.S.O., for several months, insured an organisation and thoroughness of veterinary work which had previously been absent.

The debility farms and remount depots had been largely freed from the diseases which had previously

\* Reports by Officers appointed by the Commander-in-Chief to inquire into the working of the Remount Department Abroad. "Parliamentary Paper," Cd. 995, 1902.

carried off thousands.\* The balance of the "protection stock" had received veterinary supervision, and matters as a whole during 1902 were better than they had ever previously been.

Nevertheless, unfit horses were still employed in making war, and if any failure of the Remount Service can be urged at this late period of the campaign, it is that of not grappling closely with the question of conditioning horses even during the short time the animals remained in the depots. It is true that practically every depot possessed an Eassie exercising track (see p. 129), but more than this is required for riding horses; these, in order to be conditioned, must carry a saddle and man, see p. 189.

The remount view appears to have been that it was not part of their duty to ride and train the horses, but it seems to us that it was much more their duty than that of looking after thousands of sick animals on debility farms. We fully recognise the extraordinary difficulty and expense attached to conditioning 10,000 horses a month, but the heavy financial burden thus incurred would have been cheaper than horses, and no one can doubt the saving and efficiency which would have resulted. Before the war, the question of conditioning remounts for the Field had never been thought of, possibly for the reason that the handful of horses which the War office laid down in War Establishments, as meeting the requirements of a Force, did not appear to suggest any difficulties in the way of exercise.

The conditioning of remounts in the Field for both saddle and draught work is a matter which requires the closest attention, if we are to avoid in the future the errors of the past. We do not believe that it can be satisfactorily arranged for excepting by charging the remount branch with this duty, for it is impossible to conceive two distinct departments connected with the receipt and issue of horses in war, and another charged with getting them into condition before they are given to the troops to use. The work must be centralized, and proper training establishments provided.

There are no returns after January, 1902, to show exactly the number of horses which came into the country month by month up to the proclamation of peace. In a Cable from the War Office of 26th November, 1901 (see p. 189), the numbers then being sent, in response to an increase asked for on the previous day, are put down at 10,000 to 12,000 remounts a month, and on the 24th December a Cable was received to the effect that 40,000 horses would be landed in December, January and Febru-

\* See p. 204 for the destructions in Cape Colony between September and December, 1901, inclusive. From January to May, 1902, the numbers were as follows:—

Glanders	1380
Mange	120
Debility, injuries, etc.	390

During this period 1870 died in addition to the above.

ary. The total supplied from January to June, 1902, was probably as follows:—

	Horses	Mules
Oversea remounts, less loss at sea	84,688	10,447
At sea in Dec., 1901, less loss	9367	985
Remounts obtained in S. Africa	11,898	10,520
	106,223	21,952

The loss of horses and mules during the period January to May, 1902, is estimated by us, on the basis explained at p. 141, as being in round numbers as follows:—

Horses	73,400
Mules	7800

It is again necessary to note that these losses only refer to the animals paid for, and do not include the thousands picked up\* and utilised, which were obviously fewer in 1902 than during the preceding years.

#### TOTAL LOSSES FOR THE WAR.

We may now present the total losses during the entire period of the war, and the loss we refer to is the dead loss, *i.e.*, the total number of animals which actually disappeared out of the total paid for, and exclusive of those "picked up" in South Africa.

	Dead loss	Horses	Mules
1899-1900		110,028	29,113
1901		142,603	14,433
1902		73,442	7853
<b>Totals</b>		<b>326,073</b>	<b>51,399</b>

These losses are 66.8872% for horses, and 35.3751% for mules year by year throughout the war; the numbers for each period must not be regarded as anything but approximate, for we have previously explained how they have been arrived at, but the accuracy of the totals may be accepted as they are official. See Appendix 38, p. 258, "Appendices to the Minutes of Evidence" R.C.

The circumstances attending this holocaust have formed the bulk of this history.

A great deal of scattered information regarding the loss of animals in the Field has already been recorded in these pages. A knowledge of such loss is of the utmost moment. It indicates the provision to be made for the future, and it enables a Commander to calculate beforehand what his requirements in re-inforcements are likely to be. We can only regret that the information respecting losses has not been complete or continuous, so that the cost in animals of every operation, large and small, might have been known. Even under pressure of active service brief note-making is

\* One small M.I. Column, 500 strong, alone collected 13,500 animals off the veldt in the Free State in fourteen months, and handed in 10,000 to remounts. These figures were kept by C.V.S. R. MacDonald. (See also footnote, p. 185).

In the House of Commons, 8th Feb., 1902, it was stated that 89,705 horses had been captured. The war had yet another four months to run, and it is certain the total captures amounted to over 125,000 animals.

possible, but few people appear to realise the value of such observations, and still fewer know what to record and what to reject. Regimental losses during the war are most difficult to obtain, and in many cases owing to the numerous refits of horses, no record appears to have been kept. There is one remarkable exception: Captain A. S. Head, A.V.C. (R), who served with the Inniskilling Dragoons throughout the war, kept the most careful notes of losses from all causes in this Regiment.\* His tables are unique, and as a record of untiring zeal and industry, under most disadvantageous conditions, they are never likely in the future to be approached, let alone equalled.

He tells us that from November, 1899—June, 1902, the Inniskilling Dragoons used up 3750 horses.

The distance they covered in this time measured in a straight line and on a flat surface was 6116 miles. This must at least be doubled if we are to form any notion of the amount of ground covered.

On this basis one horse was used up for every 3½ miles covered during the war.

The following table shows the strength of the Inniskilling Dragoons on landing in Africa, the number of horses that joined the regiment through the war, and the number expended during the same period.

*Income, Nov., 1899 to June, 1902.*

Strength on landing	-	406
Remounts	-	3061
"Picked up" on the Veldt	-	222
Transfers from other Regiments	-	601

Number of horses joined 4290

*Expenditure, Nov., 1899 to June, 1902.*

Sent to Veterinary Hospitals	-	1600
Missing	-	201
Returned to Remount Depot	-	202
Abandoned	-	201
Destroyed	-	595
Died	-	482
Transferred to other Regiments	-	469

Number of horses expended 3750

Strength on 31st May, 1902 540

4290

The expenditure for two and a half years of active service was equivalent to the whole regiment being re-horsed ten and a half times.

As evidence of the amount of sickness and accident occurring among horses on service, it is interesting to observe that the 4290 horses furnished 4170 admissions, so that practically every horse was sick at some time or other during the campaign. In this connection it is important to note that not a single case is recorded as sick that could perform duty of any kind. For example, there

\* "The Wear and Tear of Horses during the South African War," Lieut. A. S. Head, A.V.D.—*Journal of Comparative Pathology and Therapeutics*, 1903.

were hundreds of cases of mange in the regiment at one time or other, yet only 23 figure on the returns during two and a half years.

It is well to bear in mind the amount of regimental sickness and inefficiency, as there are people who have suggested the withdrawal of veterinary officers from regiments on service in order to place them on the line. The figures above quoted show that there is an abundance of work to be attended to, not only in treatment but in prevention. Nearly a quarter of the above cases of sickness were treated regimentally and returned to duty without burdening the hospitals. It is not bullets which kill horses on service; we have seen this over and over again in these pages. Capt. Head's figures provide us with an exact expression. Out of 4170 cases of sickness occurring in two and a half years, only 163 were due to bullet wounds, and three to shell fire! Nevertheless, the Inniskilling Dragoons saw a good deal of fighting.

The next instructive table supplied by Captain Head shows the casualties for each march or engagement throughout the war, and the distance travelled; the table only shows the actual casualties during the march, and does not include those in the intervals between the marches. It is important to observe that the mileage is the distance covered between the point of departure and the conclusion of the operations. For example, in the thirteenth entry it reads as if the distance from Krugersdorp to Johannesburg were 297 miles. The two places are close together, but twenty-eight days circuitous marching occurred before the column came to temporary rest at Johannesburg. (See Table, p. 228).

One more regimental record has been furnished through the painstaking observation of a Civil Veterinary Surgeon, Mr. Roderick MacDonald (Canadian Graduate), served for fourteen months with the 1st Mounted Infantry. The following table shows the number of horses expended during that time:—

*Income, March, 1901, to 31st May, 1902.*

Strength on 22nd March, 1901	480
Remounts	775
"Picked up" on the Veldt	360
	1615

*Expenditure, March 1901, to 31st May, 1902.*

Died, Destroyed, Killed in Action	513
Sent to Vety. Hospitals and Depots	518
Number of Horses expended	1031
Strength on 31st May, 1902	584
	1615

The regiment in fourteen months was completely re-horsed over three and a quarter times.

Of the cases treated in the Field 36% were surgical, 17% were due to lameness, 12% to skin disease, 6% to disorders of the digestive apparatus, and 29% various.

\* There were 50 killed in action and 10 lost by lightning.

## 6TH INNISKILLING DRAGOONS.

Table showing Casualties for each March, and Distance Travelled during the War.\*

Time Occupied.		March.		Strength at Date of Marching.	Died or Destroyed on March.	Abandoned on March.	Missing.	Sick at End of March.	Fit at End of March.	Distance Travelled in Miles.	Remarks showing Principal Causes of Casualties.
Date From	Date To	From.	To.								
1899 10/12	1900 6/3	Arundel	Colesburg	490	£0	Nil.	13	41	376	30	31 killed in action; 20 destroyed, bullet wounds; 15 sore backs.
1900 6/3	17/4	Colesburg	Bloemfontein	298	4	Nil.	Nil.	22	272	200	3 destroyed from exhaustion; 1 died; 10 sore backs remaining.
11/2	14/2	Modder	Kimberley	94	5	Nil.	Nil.	10	79	80	5 destroyed, bullet wounds; 6 sore backs remaining.
15/2	13/3	Kimberley	Bloemfontein	79	4	9	Nil.	20	46	100	Exhaustion cause of casualties; 12 sore backs remaining.
6/5	12/5	Bloemfontein	Kroonstad	447	48	2	Nil.	63	323	120	31 killed in action; 14 died of wounds and exhaustion; 11 sent to veterinary hospital; 28 sore backs remaining.
20/5	6/6	Kroonstad	Pretoria	372	30	70	1	72	196	175	10 died; 20 destroyed from exhaustion; 70 abandoned; 30 sore backs remaining.
9/7	3/8	Pretoria	Middelburg	556	41	23	37	24	323	120	108 sent to veterinary hospital on march, mostly sore backs and exhaustion; 18 died and 23 destroyed, exhaustion.
18/8	6/9	Middelburg	Carolina	321	10	9	5	28	306	165	59 remounts joined; 22 horses sent to veterinary hospital, of these 11 were sore backs, 5 exhaustion; 19 died and destroyed, exhaustion; 11 sore backs remaining.
10/9	14/9	Carolina	Barberton	330	6	8	6	24	286	70	2 tulip poisoning; 1 bullet wound; 3 destroyed, exhaustion; 11 sore backs remaining; 8 exhaustion.
3/10	3/11	Barberton	Pretoria	271	44	49	24	48	224	310	216 remounts joined; 97 horses sent veterinary hospital on march, of which 39 were sore backs and 48 exhaustion; 92 died or abandoned, exhaustion; 24 sore backs remaining.
11/11	21/11	Pretoria	Meyerton	416	6	Nil.	9	10	391	55	3 sore backs.
14/12	16/12	Meyerton	Krugersdorp	377	3	Nil.	Nil.	1	373	40	1 died, exhaustion; 2 destroyed, fracture.
19/12	16/1	Krugersdorp	Johannesburg	406	27	Nil.	5	48	343	297	22 remounts joined; 46 horses sent to veterinary hospital on march, of which 28 were sore backs and 14 exhaustion; 13 cases of horse sickness; 18 sore backs; 16 exhaustion cases remaining end of march.
1901 27/1	6/5	Johannesburg	Middelburg	404	112	Nil.	25	20	405	350	156 sent to veterinary hospital, consisting of 14 sore backs, the remainder exhaustion and debility; of these, 25 died horse-sickness, 6 destroyed; the remainder died and destroyed, exhaustion.
12/5	30/5	Middelburg	Steynsdorp	420	21	Nil.	10	20	454	160	71 remounts joined, and 13 Boer ponies picked up on march; 20 horses sent to sick depot.
1/6	3/7	Steynsdorp	Middelburg	454	46	Nil.	Nil.	22	394	175	8 Boer ponies taken on strength; 22 sent to sick depot.
8/7	14/7	Middelburg	Pretoria	395	2	Nil.	Nil.	8	385	85	
22/7	31/12	Orange River Colony.		385	313	Nil.	38	314	519	1314	767 remounts joined; 91 ponies taken on strength; 40 received from A.P.M. column; 314 sent to sick depot and 99 to remount depot.
1902 1/1	18/5	Orange River Colony.		519	164	Nil.	9	203	496	1610	358 remounts joined; 208 horses sent to veterinary hospital; of those died and destroyed, majority were exhaustion.
21/6	29/6	Heilbron	Bloemfontein	540	Nil.	Nil.	Nil.	Nil.	540	160	

\* This table only shows the actual casualties during the marches, and does not include those occurring in the intervals between the marches.

The 1st of June, 1902, saw South Africa officially at peace, with thousands of horses, mules and oxen to dispose of. The total number of animals in the country on that date which had been paid for was 161,400 horses, and 93,900 mules.\* After deducting those required for the Army of occupation, 140,000 horses and some 74,000 mules were in excess of requirements, and the problem was how to get rid of these as speedily as possible in view of the cost of keeping idle mouths.†

The country was devastated, and a department was formed known as the Repatriation, the function of which was to restore matters to a condition which would enable a fresh start to be made by the community. This department relieved the army of some thousands of horses and mules, but there was still a large balance available for sale which was gradually disposed of within the next few months. Prior to this, however, all horses serving with units were inspected with the object of retaining in the service only the best out of the large stock available.

The army was full of glanders and mange, the latter was obvious, the former was not. The Repatriation Department naturally insisted on the mallein test being employed for all animals purchased by them, and many thousands of inoculations were made, but in spite of this the numbers were so vast, and the urgency of regenerating the country so great, that many could not be tested for want of time and available material, and no doubt a considerable number of cases of glanders found their way into various quarters of the country. This was the more marked with those animals sold in the public market, for which no guarantee could be given, and only a limited number of which had been tested. The Civil Veterinary Departments of all the Colonies regarded this dispersal of innumerable foci of both glanders and lymphangitis with natural apprehension, but the disposal of the horses was a very necessary measure, and every reasonable effort was made to reduce the penalty of purchasing from an infected mass of material. Nevertheless, the civil departments were kept very busy for the next few years in their endeavour to stamp out both of these diseases. By about September, 1902, the Army had reduced its proportion of animals to a peace establishment.

\* The Tables published by the Royal Commission show 151,100 horses and 94,600 mules. The difference in horses is due to the reinforcements from home and oversea contingents not having been included in the War Office returns.

† There is a great discrepancy in the various Tables of the numbers of animals existing on 1st June, 1902. The figures quoted are from the Tables in the Royal Commission on the War. There are others, which show the totals as follows:—

Horses	Mules	Oxen	Donkeys
142,159	76,640	74,300	12,800

### THE BREEDS OF HORSES.

Some reference must be made to a debate on the war in the House of Commons, reported in the *Times* of 1st February, 1902. It centred around the Remount question, and frequent reference was made to horses being "bad." During the war an attempt was made to ascertain the wearing qualities and staying powers of the various breeds of oversea animals. The only oversea remount with which no fault could be found was the English "bus" horse. There were many then, and probably many to this day, who believed that the special qualities of this animal were primarily due to his being English. In the above discussion Lord Stanley destroyed this myth, by pointing out that 90% of these animals were Canadians.

In the following table \* are shown the number of remount horses and mules imported from each country during the war:—

	Horses	Mules
United Kingdom	61,484	—
South America	26,544	—
Canada	14,621	—
Australasia	23,028	—
Austria	64,157	—
U.S. of America	109,978	90,524
India	3062	1114
Spain	—	15,229
Italy	—	7004
Cyprus	—	128
Uganda	—	306

The efforts made during the war to ascertain from Commanders the wearing qualities and suitability of the different breeds of horses, comprised in the above mass of material, are tabulated in the "R.C. Appendix 58," also in "C. of E. Rem. Appendix E. No. 14." At p.218 of the latter report, is a criticism of the contradictory character of these opinions.†

No veterinary officers were asked by the Authorities to record their opinion, either on the suitability for work or soundness of the tens of thousands of imported horses. We are, nevertheless, in a position to furnish the opinion of one who saw more of every class of horse than any other veterinary officer in the country. Major Blenkinsop took full advantage of his appointment as Senior Veterinary Officer of Remounts, and we shall add his opinion‡ to those expressed in the Reports above-mentioned.

The reports on *North American Horses and Cobs* were generally to the effect that they acclimatised rapidly, bore privation well, and were capable of looking after themselves. The big horses were not liked; as one officer expressed it "the rations won't

\* "R.C. Appendix 38."

† Of three ship-loads of North American horses, all derived from the same herds, and sailing about the same time, two were reported as excellent, and the third as utterly unsuitable. "Under these circumstances it is difficult to know what to do." "Colonel de Burgh, C. of E. Rem., Appendix E., p. 360."

‡ Extracted from his Campaign Report (unpublished).

keep any animal over 14·2 alive."\* As a breed they were generally considered clumsy and not very sure footed.

Blenkinsop draws attention to the frequency with which the North American horses suffered from defective eyesight, especially cataract. Splints and spavins were common. Defective hock action, and excessively large flat feet were frequent faults. He notes the presence among these horses of a tendency for the limbs to give way on board-ship through standing, the knee curving backwards owing to rupture of supporting ligaments. This condition was not seen in other classes of horses, excepting in a few Hungarians. The bones and joints of many of the U.S. horses were wanting in development; and such animals suffered from sprain of the flexors or suspensory, if called upon to carry heavy weights for long periods. The length of the incisor teeth of these horses renders the question of "aging" rather difficult. They proved themselves hardy animals, soon recovering from debility and exhaustion, and rarely suffering from serious illness.

*Russian Horses and Cobs.* There was a consensus of opinion that this animal was too slow. He made a useful M.I. cob, but was of little use for Cavalry. Generally, the Russians are rough in their pace, hardy, and do well under exposure and short rations. Russian ponies, according to Blenkinsop, are very liable to bony diseases of the limbs; the feet are frequently defective, the wall thin and brittle. He is a hardy animal who fattens quickly, is very quiet to handle and ride, but an inveterate kicker. He can withstand long hours and short forage. The feet are very liable to congestion, especially when the animal is fat.

*South American Horses and Cobs.* These were generally condemned as slow, stubborn, clumsy. It is pointed out that good Argentines existed, and that only a few of the best were imported. General Elliott stated that "it is impossible to conceive a worse animal for service requirements," than those imported from the Argentina for the war, but that good ones exist. Blenkinsop describes the Argentine horses as very hardy, wanting in quality, and more fitted for slow draught than riding.

*Canadian Horses and Cobs.* These were generally reported upon as good hardy animals that retained their condition under stress of service. See also p. 112 of this History, which deals with the recuperative powers of Canadian horses. Lieut. Morrison † tells us that out of 137 horses, the strength of "D" Battery Royal Canadian Artillery, which landed in Africa in March, 1900, 66 were alive in the following November after a good deal of marching and

fighting.\* Blenkinsop regards the Canadian horse as more suitable for draught than for saddle. They were generally sound horses, and did good work in the Field. He notes the presence among them of roaring and the frequency of defective eyesight.

*English Horses and Cobs.* There was a consensus of opinion that the English horse required to become acclimatised before the best results were realised. The bigger he is the more unsuitable he becomes; he must be well fed.† "The English horses that, owing to good fortune, or to exceptionally strong constitutions, have not died before they became properly acclimatised, are the best horses for work in the Field"‡ (Col. Rawlinson). Another officer says:—"A bit of a fool when put immediately into the Field, as he has been so well cared for; he takes time to adapt himself to strange conditions of service, such as grazing, standing still, watering, etc., and is a bit like his British rider in that respect" (General W. Knox). Blenkinsop regarded the English horse as the most technically unsound of all those imported. He points out faults which render him a bad horse on service, i.e., constantly kicking, bad grazer, difficult to drive in mobs, and slow to recuperate from debility and exhaustion the result of hard work. A very large percentage became roarers after they had been in South Africa any length of time. With all his faults he admits he was the best animal imported into the country, but he required feeding, careful attention, and protection from the weather until acclimatised. Blenkinsop notes the large percentage of horses shipped as English which were not so bred.

*Australasian Horses* These animals take a year to acclimatise in India, and they require time in

\* As an example of the vitality of the Canadian horse, he relates the story of one left behind for dead owing to exhaustion. The animal subsequently struggled along and came into camp, and the men gave him a cheer.

† Other information bearing on this point has already been sufficiently referred to at pp. 122, 133. From the large unsuitable horse, which the Director-General of the Veterinary Service urged the Inspector-General of Remounts not to buy, the Remount Department, with two years experience in the Field, had come down to the polo pony stamp, see footnote p. 122, also Cable 104, Cd. 963, to the War Office, which runs as follows:—"English horses arriving still too heavy. Well-bred, weight-carrying polo pony is the ideal required for all mounted troops, who now carry little on the saddle."

Well-bred weight-carrying polo ponies, to the number of 10,000 or 12,000 a month, were now asked for! Where was it supposed they were to come from, even if they could have been purchased at remount price?

The Court of Enquiry into the administration of the Army Remount Department, was the only body distinctly charged with the duty of inquiring into the question of whether the proper stamp of horse had been provided for the war. It is somewhat significant that Colonel Duck, whose evidence is given at p. 122 of this History, was never called before it, so that the initial blunder made by the Remount Department in providing, against skilled advice, a class of horse utterly unsuited to the country, does not appear in the Report subsequently presented to Parliament.

‡ In this connection, see the remarks, pp. 134, 135.

\* Even the Remount Authorities must by this time have become convinced of the value of the small horse. In a letter to the War Office the Assistant Inspector of Remounts, S. A., under date 27th November, 1901, says:—"Even . . . keep demanding ponies, which are the only things they can feed enough to keep them alive." Nevertheless, in his report to the War Office, subsequently printed as a Parliamentary Paper, there is no mention of starvation rations.

† "With the Guns in South Africa."

South Africa. All big and leggy horses failed; the others did well if given time. Like English horses they require to be well fed. They are slow at recovering from exhaustion, a bad feature in a soldier's horse. Australian horses are noted by Blenkinsop as liable to respiratory trouble, especially catarrh, and bilious fever. They require a long time for recovery after a voyage. The muscular development is imperfect, and they need long and continuous exercise and feeding before being fit for service. He regards the New Zealand horse as not only better developed but a far more useful animal.

*Hungarian Horses.* Universally condemned. Blenkinsop notes the "softness" of Hungarian horses, their liability to congested feet, to saddle and girth galls, their lack of physical development, and their difficulty in recovering condition after emaciation.

No special report is published dealing with the horse of South Africa, perhaps none was necessary. He was superb, though our Remount Department would not look at him until compelled.\* Colonel Thorneycroft, who raised and commanded an Irregular Regiment of Mounted Infantry during the war, told the Commission, "R.C. Appendix 52," p.353, that a very large number of the original animals which came to him on raising the regiment *went all through the campaign.*† They kept their condition in a wonderful manner considering the hard work they performed. Many were small ponies, but "they seemed to carry the heavy weight with far greater ease to themselves than a big horse."

General Plumer ("R.C. Evid., Q.18034"), in referring to the South African horse, said that nearly 30% of his were effective at the end of twelve months' service in the Field. This he attributed to there being time to get them into condition before war broke out. He stated that he himself rode the same horse throughout the whole campaign. "I hardly had another horse."‡ We have seen the character of the work in which General Plumer was engaged. Blenkinsop draws attention to the immunity of the South African horse to disease, his defective symmetry and conformation, and the surprising amount of work that a veritable weevil could perform. Their peculiar short teeth and coarse grazing render their age very difficult to judge.

It is, however, quite unnecessary to bring forward any other evidence of the wonderful vitality of these horses, than that afforded by the stout and prolonged resistance offered by an enemy to whom marching on foot was unknown.

Lord Stanley, in the House of Commons' "bad horse" debate, previously referred to, struck one of the few practical notes which appeared throughout,

\* See pp. 123 (Statement by Q.M.G.), 131, 132, 133.

† The italics are ours.

‡ He adds that he only paid £19 10s. for this animal, and that his last march was one of 60 miles.

when he stated "that the real secret of a good remount was condition." It is impossible to say whether a remount is going to be good or bad, whose physical condition is such that he is dead in a few days or even hours after being issued. He never has a chance of showing what he is made of. The remarkable divergence of views to be met with in the Appendix 58 of the Royal Commission, and that tabulated in the "C. of E. Rem.," App.E 14, can readily be explained on this basis. It was the previously hard condition of the "bus" horse which enabled him to recover rapidly from the sea voyage and put on a good front. Further, he was not hustled; the majority of these horses went to Natal where they had by no means a hard time at the early part of the war. It is not intended to suggest that "bad horses" were not sent from overseas. The ill-selected, underbred, cheap Argentine could never have been anything but what he was, but he certainly never had a chance. The Hungarian "flat-catcher," even when conditioned, was not of the "cut and come again" type, and the big horse of any breed is a "bad horse" for war. Condition will help, but not remove, "sickle hocks," overshot fetlocks, "turned-out" toes, and long backs; nevertheless, the wholesale charge of "bad horses," heard within and without the House of Commons, represents in the main the loose expression of opinion of men, who, with no technical knowledge of a highly technical question, are led away either by their own ignorance or that of others.

We have no other object to serve than that of historical accuracy and fair criticism, whether to partisan or opponent. When the enormous numbers of animals purchased for South Africa are borne in mind, it is not a matter for surprise that "bad" ones were to be found. Does no dealer ever buy a bad horse? Does no skilled layman every buy one he regrets having taken? What, therefore, was to be expected when officers of limited or no knowledge of the work † were sent with a blank cheque to various parts of the globe, to learn at the public expense one of the most difficult branches of trade? If a merchant were compelled to send inexperienced men to buy tea and sugar on his behalf he would expect mistakes to be made.

\* The following are the official Cables, Cd. 963, in which specific instances of bad horses are reported:—

- Cable 68. December 19th, 1900. "Hungarian horses condemned as 'flat-catchers' . . . Big horses, especially Australians, last no time."
- Cable 81. May 1st, 1901. "American horses arriving too leggy and loose made."
- Cable 95. October 15th, 1901. Reporting on a consignment of horses from Australia says, "Attribute bad condition to class of animal. Big, long-legged, ragged-hipped, coarse horses. . . ."
- Cable 112. January 15th, 1902. Reporting that the horses of the Bays were of the wrong stamp to last in Africa. Asks for greater care in selection generally.
- Cable 114. January 22nd, 1902. "Considerable percentage of horses landed lack compact formation . . . Australian horses specially badly selected."

† See this History, p. 124.

We doubt whether the purchasing officers of no experience had any conception of the difficulty of their task. That they had no conception of their own ignorance is, we think, undoubted, for they were not compelled to accept the position. Further, did they not all belong to the mounted branches of the Service, which of itself, *from an Army point of view*, was a sufficient guarantee of a knowledge of horses? It was the fair price paid by the State and the enormous numbers purchased which saved the inexperienced buyer. It is absurd to suppose that when animals are being bought by tens of thousands only undesirables are presented. Had a better price been paid for the Argentine a better class of animal would have been obtained. The purchase of big horses must not be laid to the charge of the remount purchasing officer. The War Office fixes the standard of height, and from this scale the purchaser is not permitted to depart. We submit that the purchasing officers made a good average selection, for the reason that in dealing with such enormous numbers, ordinary care being exercised, an average must be reached which represents the horse of the country. It is presumed that the Authorities were satisfied that the horse of the country was suited for their work, or else the purchasing officer would never have been sent there.

In those cases, such as Hungary, where the horse of the country failed, the charge must not be laid against the purchasing officer. The only possible exception to this dictum is the horse of Australia, which was, from Indian experience, repeatedly reported as badly selected. But may not this have been due to the fact that the Australian horses employed by the Army in India are carefully selected, after importation, from four times the number required, and therefore do not represent the general type of the horse of the country? It

\* Lord Downe, in his "Report on the Remount Operations in Australia—Parliamentary Paper, Cd. 995," says:—

"The general idea in England is, that Australia swarms with horses, and that good horses are to be bought like rabbits—for next to nothing . . . The breeders mostly breed for racing purposes, and thus the greater part of the surplus horses are weeds . . . In another part of the same report the Queensland horse is described as "light, weedy, and badly nourished . . . totally unbroken and not used to be handled like paddock-bred horses. . . . Many of these found their way to South Africa."

"There are doubtless large numbers of good, useful horses bred, but beyond the local requirements and the

is stated, "R.C.", Q, 13,065, that the purchasing officer in Australia rejected 50% of those presented for sale. Nevertheless, it appears to us that the price he paid was not sufficiently high to obtain a horse suitable for immediate use.

The smaller the numbers purchased the greater chance for ignorance and inexperience to demonstrate their presence. Few wars in the future, let us hope, will afford two-and-a-half years for the training of its remount officers, and experience extending to the purchase of half-a-million of animals; it must not, therefore, be imagined that we advocate the inexperienced and ignorant being sent purchasing in time of war. Where, however, are skilled purchasers in sufficient numbers to be obtained? Personally, we would select from amongst the largest dealers in the country, creating rigid safeguards, and giving them the salary of a Cabinet Minister while employed. Such a scheme would be economically sound.

The purchasing officer is not responsible for soundness; the cry of "unsound horses" was at times as frequent and undeserved as that of "bad horses." Some fifty cases of ringbone, for example, were reported to have been sent in a single consignment from Austria!\* Imagine the amount of work required by the dealer and his agents, to "beat up" a sufficient number of cases of this disease to secure the passage of fifty through the first line of defence at the place of purchase? Extravagant charges of bad horses and wholesale unsoundness may be dismissed.

Indian market . . . which takes 6000 to 8000 horses a year, there has been no great demand outside."

In describing the difficulties of a Remount Agent dealing direct with breeders and small men, Lord Downe goes on to say that the general system of horse disposal in the country is by means of large auctions. "Is it possible at any public auction, where horses are sold at an average rate of one a minute, for an amateur buyer in a strange country to compete with professionals at their own trade, and in their own country?"

The trials, annoyances, hard work and hardships, of purchasing officers form no part of this History; they were very real. The good work done in the various countries has been buried beneath the obloquy created by the disastrous organisation of this service before the War. "Two Years with Remount Commissions," by H. Sessions, F.R.C.V.S., may be read with profit and pleasure.

\* See Report "C. of E. Remounts," para. 203.

## PART III.

There are several special features which could not be conveniently dealt with in the text, and these it is intended shall form the subject of this part of the History. Some, like horsemastership, have already been frequently referred to. The transport of horses by sea and rail; the care of transport animals in the Field; shoeing; sorebacks; epizootic diseases and their management; acclimatisation; poisonous plants, the supply and accounting for equipment, etc., are all questions which, considering their importance, it has not been possible hitherto to notice with sufficient fulness.

### *HORSEMASTERSHIP.*

Under this designation is comprised the very large question of the care and management of horses under all conditions. It embraces every subject which contributes to the well-being of the animal, a knowledge of which is essential to his health and preservation. This information has to be gained by prolonged practical experience; it cannot be learned on a campaign, but only as the result of a previous apprenticeship. So ignorant are the majority of Staff Officers of this subject—from causes referred to at pp. 115, 192—that it is the exception to find amongst them any who, without previous experience in the mounted branches, or the instincts of a horseman, have any knowledge of the subject, or are aware of its extraordinary importance. The idea with such is, apparently, that if a man is able to keep his place in the saddle, everything connected with the care and management of the horse automatically follows. Unless this is the view held, it is impossible to explain the policy which brings thousands of irregular horsemen into existence in an emergency. Take the case of the 1901 Contingent of Imperial Yeomanry. We have it on the authority of Lord Chesham, Inspector-General of Imperial Yeomanry,\* that 75% of the men had not been on a horse before they passed the riding school test at home, and that 25% had ridden very little. Apart from the question of sending such material as mounted troops into the Field—a matter which does not concern us—what is to become of the wretched animals of which these men are placed in charge? The Yeomanry of 1901 are not the only examples of this class of organisation; we have met with it in the regular

forces, especially in February, 1900, p. 31, and in all cases it has resulted in a heavy loss of animal life and inefficiency.

It would seem, therefore, that the responsible authorities who call into existence mounted troops from untrained material, are unconscious that the horse needs certain essential requirements, which can only be furnished by previous knowledge, and unremitting care and attention.

It would be a fair assumption that regular troops, trained to the mounted service, should be able to show the result of their experience and knowledge of horsemastership, by the better preservation of their horses and a vastly lower rate of inefficiency as compared with those not so skilled. Unfortunately, during the South African campaign, this was not so; with the exception of the Artillery the mounted branches showed, with but few exceptions, a deplorable deficiency in this vitally important question; so marked was this that it formed one of the questions which the Royal Commission on the War was specially directed to investigate. Before referring to the results of this inquiry, it will be well to see whether any conditions existed before the war in the Cavalry arm, which can help to explain this astonishing fact. It is a long story with which this History cannot be burdened, but only the essential features stated.

As a matter of fact they have already been hinted at on p. 117. The original organisation of the Cavalry gave the individual officers no control over their horses or interest in their management; diet stable management and work were regulated by the colonel commanding the regiment, and the troop officers obtained no experience, but were tied down to a lifeless routine which was as well, and frequently better, carried out by the Sergeant-Major of the troop as by an officer. Under this system a horse could not be taken out of the stable without the colonel's permission. Shortly before the war all this was changed in principle, if not in practice. It is a very hard matter to effect a radical change in organisation in a day, especially in an old army like ours which lives on tradition, and is intensely conservative. Under the new system the squadron and not the troop became the unit, and squadron commanders were, at least in theory, given actual command of both horses and men, and held responsible for their training and well-being. It is no matter for wonder that many were by no means anxious for such independence, for it carried with it

\* "R.C. Evid." Vol. i., p. 288, Q. 6731.

responsibility which came too late in life to be welcomed. Time therefore was necessary for the new ideas to develop, and for a new generation of officers to come into existence. This, perhaps, was only realised by the relatively small proportion of men in the world who think. Meanwhile, far-reaching changes were under consideration in connection with the horse question, one of the earliest being that the squadron officers were to carry out the training of remounts and prepare them to take their place in the ranks. To enable this to be effected it was recognised that previous training of the officers was essential, and selected officers were sent abroad to see how these things were managed in Germany, France and Italy. In these countries the squadron system was almost as old as the army, and it is quite true that under the conditions of military service in these countries a squadron system of horse-training had become so deeply a part of Cavalry organisation, that no difficulty was experienced in carrying it out, as opposed to the system in this country of having one expert in the regiment who trained the whole of the horses for the various squadrons. We do not defend the latter system; it was radically defective, but it gave each regiment a trained officer—who was the selection from among hundreds of men all specially trained by a long course of Riding School work—for the responsible and technical duty of converting the wild and raw material into the steady, handy troop-horse.

The officers deputed to visit the Continental armies brought back with them much valuable information, and some which was bad. In France they saw a handful of men and horses, the pick of many thousands, go through a Riding School performance such as would have been a credit to the finest circus in the world. The riding of these men is superb, the handling and management of their well-broken horses a something to remember, the whole carried out before a crowded house, with a solemnity and silence that an occasion of such dignity demands. It was a demonstration in the methods of the High School of Horsemanship, first developed in Italy during the 16th Century, before mediæval picturesqueness and pomp had found its natural limits.<sup>o</sup> The British delegates on their

return from the Continent were enthusiastic of the new principles. It seemed, however, to escape observation that the Continental system of training was carried out by men who made the army a life calling, it was their profession. Their means did not admit, as with us, of coming to the Service for a few years and then retiring when it suited them; they came to it for life, and accordingly, under long and skilful early training, became expert. The knowledge and experience gained by officers of our native Cavalry in India is identical in nature.

Among the absolutely bad principles in horse management brought back by the British delegates was that of the Continental system of stable bedding. It is usual from motives of economy (?) to leave the bedding down in the stables of France, Germany and Italy for periods of three or four months at a time; meanwhile, the dung and urine are covered over daily with fresh straw and well trodden by the horse into a firm, yet elastic bed, which grows. When it has assumed an inconvenient height it is removed, and the putrid condition of the material and its overpowering stench when the mass is opened up cannot be adequately described. This pernicious system of Continental bedding at once proved popular. The officers liked it: the fermentation of the mass kept the stable warm, and the saving in bedding gave them a larger ration of hay or corn to work with: the men liked it because it represented a fraction of the usual labour. The veterinary service condemned it as insanitary and destructive to the feet. British stable management had hitherto been regarded as the acme of perfection, the keynote of which was cleanliness.

By the adoption of this filthy system in our Cavalry stables, the hands of the clock of progress were put back. The authorities apparently unwilling to destroy the initiative the new squadron system was intended to encourage, took no action to abolish the disgusting practice. At this moment war broke out.

It is evident that the sudden transition from helpless inactivity and hopeless routine, to chartered and uncontrolled licence was bad, for the reason that the needful knowledge had not in the meantime become acquired. It would have needed twenty years to have changed successfully the working of the machine—it barely had as many months. In consequence, the Cavalry entered upon the war in South Africa not only with an in-

right and left, and passage, and if he can do these six things, he is quite fit to go into the ranks, and you ought to be able to teach him these six things in four months."

\* "The necessity for ample means [in the Cavalry] bars efficiency. A rich man seldom remains long enough in the service, nor can he be said to make it his profession; he consequently lacks the necessary incentive to advance himself."—Earl of Scarborough, "R.C. App. 23," p. 170.

In his evidence before the Royal Commission, Major-Gen. Marshall, an Artillery officer, in Q. 18,571, says the young officer "comes into the Artillery to make it a profession, and he is in every way encouraged to do so. It is not true of the Artillery officer that keenness in his work is unfashionable."—"R.C. Evid.," Vol. ii., p. 364.

\* At one time the Cavalry horse remained so long under training that his joints were partly worn out before he had completed his elaborate education. The bulk of his work took place in the School, the result being that, at the time we are speaking of, not 10% of the Cavalry horses would go alone. If a man was wanted from the ranks to take a message a volunteer had to be called for. All that has now changed, thanks to the younger school of thought. General Sir Douglas Haig (who was Assistant Adjutant General to the Cavalry Division during the War) gave the Royal Commission his views on the subject of the military training of horses:—

"The men must do less 'show riding.' The Riding School has come to be regarded as the end and object of our training, instead of only being a means to an end . . . Q. 19,488. "There are only six things you want to teach the individual man in riding—to start his horse, to stop his horse, to back, to turn to the right and left, to circle to the

adequate knowledge of the question of practical horsemastership, but were still suffering from the effects, and even continuing to labour under the vicious system, of centralisation and absence of authority.

The great contrast this presents to the Artillery arm may be gathered from the remarks on this question at p.117. Here were two branches of the service, both men and officers respectively, recruited from the same class. Under the system of undivided individual responsibility and sound regimental creed, the one remained a self-reliant, self-contained branch devoted to the welfare of its horses; the other with no regimental creed, with no personal control, constantly looking to higher authority for permission to act, and ignorant what to do in its absence, began and ended in failure. These things cannot be learned on service; the principles, at least, must be brought into the Field.

In this matter of failure we write broadly. There were individual examples of fine horsemastership, and knowledgeable officers, who, given a free hand, developed to a remarkable extent, but these few were unable to leaven the mass, and above all the private soldier could not now be reached. The artillery driver has been taught for a hundred years to live for his horse, and that without it he is a useless encumbrance; the private of Cavalry was never so taught. He was trained to believe that his horse was a conveyance, that to be seen off its back was a dishonour and reduced him to the footing of an infantry soldier! He was never trained in the belief that his horse was his first and sole consideration. Individualism in the Cavalry soldier in this respect is required a hundred-fold more than in the Artillery, where teams work together under the eye of a non-commissioned officer. In Cavalry, men are frequently by themselves, away from the eye of a controlling superior. It ought ever to have been an established Cavalry principle that none but men capable of taking care of their horses would be retained in an arm of the service, which, for many reasons, is regarded as possessing attractions denied the others. Such, however, has not been the case.\* To go back as far as the Peninsular War is quite sufficient for our purpose, it was a matter of notoriety how badly the British Dragoon looked after his horse, while the German Hussar working side by side with him had his animal fit.† At that time the Artillery were as

particular regarding the care of their horses as they are to-day. They had a creed, the Cavalry had none. They had none in the Crimea. Lord Cardigan allowed the horses of the Light Brigade to starve rather than employ his idle regiments on transport duty, and if this was the spirit shown by the Commander it is no subject for wonder that it existed through all ranks. From the Crimea to the Egyptian Campaign of 1882 was sufficient interval to have placed matters on a sound footing, but nothing was done. A few days campaigning in Egypt saw the Cavalry disappear; underfed and overweighted they melted away like ice in a summer sun. Starved horses were seen standing next to a growing corn crop, of which those in authority failed to take advantage, for the reason, it is said, they did not recognise it was a forage plant, and perhaps because they were waiting for authority.

In other matters they showed an equal want of initiative, perhaps even interest. Sore backs, the bane of Cavalry, had never been systematically studied; the regulation method of dealing with them was to punish the man who rode the horse. As to the weight carried, it was not until some time after the Egyptian war that it was recognised as crushing, and equivalent to the weight of a second rider. In fact, there were old and responsible officers of Cavalry who believed that the greater the weight placed on the horse's back, the greater care shown by the rider to prevent it causing damage! The question as to whether the horse could effectively carry it never seems to have been considered, yet all these were hunting, and the majority, racing men.

The first real insight into what Cavalry were capable of accomplishing under skilled management was obtained in the Nile Campaign of 1884-85, when the 19th Hussars showed what horses and men could do under conditions as severe as can well nigh be imagined. The resuscitation of the Cavalry arm began from that small nucleus of earnest officers and well-trained men; crystallization had begun when the war in South Africa broke out; the crystals were small and imperfect, and readily dissolved on agitation; they soon received this stimulus and at the hands of the authorities.

Cavalry is a very expensive arm to create, train, and maintain. On arrival in South Africa the portion which passed into Cape Colony found that the rations for their horses was to consist of 10lb. grain and no hay, see p.14, *et seq.* The hay ration was to be obtained by grazing horses where no grass existed. It further seemed to have been forgotten that, at enormous expense, the regiments had been sent out

Dragoon was so great, that the German Legion could always put 100 horses in the ranks to our 10.

Mercer says the great distinction between the German and British Dragoon was the affection for and care of the former for his horse. The German would sell everything to feed his horse, while the British Dragoon looked upon the animal as a curse and source of perpetual drudgery to himself.

\* General Rimington, in his evidence before the Royal Commission, vol. ii., p.585, says:—"I found throughout the war, with all sorts of troops, and all ranks, that care of horses comes naturally to very few men, except those brought up from boyhood with horses. As a rule, all other soldiers only do what they are compelled to do, and at best regard the care of their horses as a very weary and irksome necessity."

† "Military Opinions," Field Marshal Sir J. Burgoyne; "Diary of the Waterloo Campaign," Captain Mercer, R.A. Sir John Burgoyne said that the difference in care bestowed on the horses by the British and German

to fight, and that grazing was a slow process \* which could only be carried out during the day, at which time they were occupied with the business for which they existed. Over and over again in this History has attention been drawn to this question, and there is no need here for further elaboration, the point is self-evident. The action of the authorities was viewed with dismay. Every application for hay was met by instructions to graze, and for an increased corn ration by the reply that only a single line existed, the capacity of which was limited. Is it any wonder that under these conditions the daily wasting of horses from circumstances beyond the control of those in charge was viewed with something approaching indifference? It is difficult to maintain interest in the condition of horses which are being deliberately semi-starved by authority, in spite of every representation! Anything in this connection more appalling cannot be imagined, and as our History shows, before the Cavalry Division had reached Bloemfontein its trained horses had disappeared. This system of horsemastership was not calculated to stimulate the zeal of officers or men, and among other far-reaching pernicious effects, it fostered a spirit of indifference. The liberal supply of horses put the final touches to this hopeless picture. Who can possibly declare the horse supply to have failed who has read the figures contained in these pages? It was good, far too good, and led, as all excess of supply leads, to waste. The moment officers and men realised that another horse was forthcoming when the present one was ridden to a standstill, care was thrown to the winds. They were not ignorant of the fact that the animals so supplied were hopelessly unfit; that was not their responsibility, for they were powerless to prevent the issues. The traditions of their service fostered indifference. It is difficult to find a word which expresses their acquiescence in men sitting on their horses' backs when they ought to be standing on their feet, or leading their horses on the march; or of squadrons not grazing, if even only for a few minutes, while standing in long grass waiting for orders; or of passing a water supply without slaking their horses' thirst; or of taking no systematic steps to prevent overloading the animal with unauthorised material, a thing every soldier is liable to do on service. The produce of a neighbouring farm hung to one side of the saddle causes it to heel over and press on the withers; a chair for firewood hanging from the rear arch, or a farm door resting on the root of the neck, are not features which can escape observation, and are totally ruinous to horses' backs.

The want of kindness shown by men to their horses cannot have escaped the notice of their officers. The utter want of sympathy with animal suffering; the extraordinary indifference of the soldier to the welfare of the horse on whose powers

\* It takes a horse one hour to eat three pounds of hay. When he has to find his fodder and cut it himself, he will naturally eat less than this in a given time.

of endurance his life may at any moment depend; the vicious spurring and "jabbing" in the mouth at every fault, show how much there is yet to inculcate if animals on service, be they well fed or starved, are to receive humane treatment at the hands of those to whose care they are committed (see p. 79).

To avoid any possible charge of bias, it is desirable here to reproduce a summary of the evidence of some Commanders in the war on the subject of Horsemastership, taken from the Evidence in the Royal Commission.

Lord Roberts, himself a horsemaster, said it was not sufficient that Cavalry or Mounted Infantry should be able to ride, but they must know how to get the utmost out of their horses by good treatment and never-failing consideration of their wants. "Until the soldier is held directly responsible for, and takes a personal interest in, the condition of his charger, until he learns to rely on his own common sense and experience, not merely on the orders of his superior, that this condition is maintained, our horsemastership is sure to be indifferent." † We have seen in this History ‡ the steps he took in this matter almost as soon as he landed, and the orders published, not only as regards horses, but mules and transport oxen.

Lord Kitchener stated that the care of horses required more attention; he said it was difficult in time of war to instruct men in horse management, and that they should receive more careful instruction in this matter during peace. §

General Buller said the horsemastership was bad. \*\*

General French stated that the regimental officers and men were very careful of their horses, but their training was too narrow; they understood stable management better than the care of horses in the Field. Of this he gave examples of the want of knowledge in the selection of grazing ground at the early part of the war, through ignorance of the African veldt; the want of knowledge how to utilise the food grains, such as barley, maize, wheat, to be found on farms, by either overfeeding with them, and so causing digestive trouble and laminitis, or neglecting the available supplies through excessive caution. Horsemastership in the Field, he states, is altogether a matter of feeding. ¶

General Lord Methuen, speaking of Yeomanry and Colonial horsemastership, said they had no idea how to save a horse or nurse a tender back. He found by marching instead of re-mounting the dismounted men that their care improved. §

§ .. Q. 14,219, 14,220, p. 123.

General Ian Hamilton could not see much to choose between the horsemastership of the Cavalry, Mounted Infantry, Oversea Colonials, or National Scouts. He adds that the only class of men he met with who were constantly and eagerly on the look out for a chance to save their horses and give them a bite of grass or a drink of water, were those South African Colonials who rode their own horses.\*

General Hunter stated that in the Mounted Infantry a man who was suddenly taken off his feet and put on a horse needed to be taught horsemastership; horsemastership indicates previous training, you cannot be a master without learning.†

General Gatacre held that the knowledge of how to save horses comes with experience; it cannot be taught in a year or two. Much training is required to teach a man to be in sympathy with his horse.‡

General Bruce Hamilton believed that horsemastership is very much a question of discipline.\*\*

General Warren thought that officers of all ranks were not sufficiently taught about horses, and suggested that if every officer could shoe a horse, and know something about the ways of one, things would be much better.††

General C. E. Knox said the Mounted Infantry must be taught how to look after and take care of their horses; in his opinion they do not know anything about this, and the Cavalry were much the same.‡‡

General Rundle said the horsemastership was very bad. It was impossible to get the men to dismount from their horses when halted; they would sit on them for half-an-hour unless somebody told them to get off. The experience of this witness was confined to irregular mounted troops. §§

General Plumer believed that horsemastership and discipline go hand in hand. The man must always be thinking about his horse. §

Colonel Haig (D.A.A.G., Cavalry Division) said all ranks in the Cavalry must be taught to realise that the horse is their chief arm and how to look after him in the Field. Hitherto there has been too much pampering in peace time.\* \*

Brig.-General Rimington. This officer early in the campaign drew up "Notes on Horsemastership," in which he emphasised the necessity for supervision by officers; grazing at every possible

opportunity; men never to sit on their horses at a halt; to off-saddle at every opportunity, if only for five minutes; the kit on the horse to be reduced to a minimum; men to dismount and walk down (but never up) all hills. Men giving horses a sore back to be made to walk. In his evidence, General Rimington, in referring to the Mounted Infantryman, said, "when put on a horse, he did not know what to do with it," and added, that a man once said to him, he "did not know whether to feed it on beef or mutton." \*

\* Idem, Q. 12,652, *et seq.*, p. 27. This cavalry general's evidence is of such importance, that we reproduce a fuller summary than the above. At the outbreak of the war he raised an irregular Corps of Scouts; he gave the Royal Commission an outline of his orders on Horsemastership, which were drawn up for their guidance:—

"Grazing was resorted to at every possible chance. The moment a man gets off his horse he throws the reins over his horse's head, and the horse stands and grazes, which makes him quiet for dismounted work and so on, and he is also nibbling whenever the man is dismounted.

"The men are never allowed to sit on their horses at a halt. That was a great fault with most troops, and wants some legislation. I mean to say that we ought to try and get a rule about that in future, that a man should never sit on his horse at a halt. The ordinary cavalry soldier does; he gets into a habit of it in the Riding School.

"The horses were off-saddled at every opportunity, even for five minutes. Our saddles were light, we had not much on them, it was no trouble to the man to unlance the (cynch) girth. We had no breast plate or crupper. . . . In the retreat from Sannah's Post my men off-saddled while the Boers were pressing us so . . . and were watering and feeding them. The Boers were very near, and things were pretty tight, but the habit was a good one. I was rather annoyed, because I thought we should not get away. I thought it was playing it rather fine.

"The kit carried on the horse was reduced to a minimum. That is absolutely necessary in any mounted operations; you cannot do anything if you have a heavy kit on the horses . . . It was the ordinary shooting kit that a man would go out in to shoot buck. . . . At the end of the war we reduced the Cavalry Kit in my regiment to the same thing.

"The men were made to dismount and walk down (never up) all hills. . . . It is no good taking the man off the horse when he is going up hill . . . because the saddle gets well shifted back, which is a good thing, and a man does not mind walking down hill; whereas, if you put a saddle and big weight on your horse going down hill, you distress it more than by going up hill. . . . If you are scouting you want to be on the horse going up hill, because you do not know what is going to happen when you get to the top. When you are at the top you have seen what is there."

It is important in this respect to learn the difference between cavalry and artillery horsemastership.

Colonel Davidson, in his evidence before the Royal Commission:—Q. 18,660, in speaking of artillery operating with cavalry, complained that the artillery had insufficient halts.

"If anything goes wrong with a cavalryman's horse he can stop and put it right, and canter up and rejoin his squadron;" but if a horse in a gun is beginning to get wrong, unless you have a halt, and can take him out and put another one in, or readjust his harness, that horse will begin to hang back, and he will kill the other five horses in that team. I do not know that I am allowed to say exactly what I think, but I think that killed a great many splendid horses which, with the best of horse-management, would have done the whole campaign. We sometimes went 25 miles with only two halts, whereas, by trying more to

General Baden Powell regarded efficient horsemastership as essential to the success of Cavalry. He urged that it cannot be picked up at once by hastily organised troops. It is a matter of experience and training, but even yet requires developing in the Cavalry.\*

General Brabazon. The evidence of this officer had better be given in his own words:—

"I really believe, although I say it, that I was the only man, certainly the only General Officer, who tried to stop the abuse of horse-flesh. I never saw such shameful abuse of horse-flesh in the whole course of my life as existed throughout the whole campaign, and not an attempt was made to check it . . . . One never saw an irregular man go except at a gallop, he thought it was the normal pace for a horse . . . . The horses were abused in every sort of way, and there was no attempt made to check it. I tried my little best with the draught animals and with the mounted troops, but could not do much. I was shocked, I was horrified. We might have saved at least 25 if not 50% of our animals if proper care had been taken of them. But that must come from the head; everything filters down from the top, from the head, and I do not think from the very tip-top of the whole lot they cared twopence how horses or draught animals were abused." †

The pages of this History show, in the reproduction of the orders bearing on the care of animals, that this matter had not been neglected as the witness believed.

The Earl of Scarborough handed in a Paper to the Royal Commission, entitled "Secretary of State for War's Scheme with regard to the Yeomanry." In this he says ‡ "As a rule officers (Cavalry) are bad horsemasters, having no idea of taking care of their horses. This important part of their duties is utterly neglected".

The extracts made from the evidence of the above officers point very conclusively to the fact that the care and management of animals left much to be desired in all branches, excepting the Artillery. On the latter point there was a consensus of evidence as to the care and devotion shown by all ranks, °°

halt where there was grass, and letting the horses get their heads down, we should have done the whole of that march without losing any horses."

Q. 18,663. "If you trot through heavy sand, you knock your horses up; if you trot up a steep hill, you knock your horses up; but if you walk up a steep hill, and take advantage of the ground being with the collar—I am only talking of wheels, and not of cavalry horses,—in that way you can save your horses, so that you can do your work, and especially halting where there is grass, instead of halting where there is no grass."

Q. 18,673. "The cavalry must give the pace, but cavalry can often crown hills first, and they might let the artillery come up slowly, whereas, we marched absolutely dressing with the cavalry the whole way. It is a question of treating the wheels on the march according to the nature of the ground."

\* R.C. Evid., Q. 19,820, p. 425.

‡ R.C. Appendix No. 23, p. 170.

°° In the "Report of the Royal Commission on the War," p. 47, para. 82, it is stated "It was generally agreed that the Royal Artillery knew how to take great care of their horses. . . ."

which, as we have seen earlier (p. 117), is due to an admirable regimental system over a century old; positive proof, if any were required, that this information can only be gained during peace and enforced by discipline.\*

In summing up the question of horsemastership we have seen that the mounted Infantry failed owing to their ignorance of the work; the Cavalry through the effects of a vicious system, abolished but not obliterated when war broke out, which placed the management of its horses in peace in the hands of the Colonel and Adjutant and in war in the hands of the Squadron Officers.

We have attempted nothing more than to deal with the question of Horsemastership in War as a whole, the details can unfortunately find no place in these pages. A simple and safe method of picketing is still required. The necessity for blankets has yet to be decided, and their possible advantage placed against their weight, especially when wet and muddy. The transport they occupy would be far better devoted to the carriage of hay. As to the extra comfort they afford, a third of them are under the horses feet at night, and there is no practical method on Service of keeping them in their place. As a means of spreading contagious skin disease they are unrivalled. Moreover, the well-fed horse, unclipped on neck, shoulders, back, loins and quarters does not need one. Colonel Thorneycroft, in a Paper laid before the Royal

\* It must not be supposed that the organisation of the Artillery has saved it from making huge blunders. It is as conservative as every other branch of the Army; the spirit of what was good enough for one's grandfather is not the spirit of progress. Great Britain woke up one morning to find that its Artillery was obsolete, and of no more use against modern Artillery than a pop-gun. The Artillery had held on to muzzle-loading guns when every single nation in Europe was armed with a breech-loader. It held on to shaft-draught as being essential for guns when all the Artillery of the world used pole-draught. It used collars and enormously heavy harness when other nations were employing breast-harness, and the lightest material in construction. It did not change one of the above features on its own initiative, but only under the pressure of dire necessity. It has, indeed, been said that until recent years harness and fat horses formed a far more important part of the Artillery creed than guns. Certain it is they went to South Africa with ammunition which was defective in range, and had to wait for months, until a fuse could be manufactured at home, before they could compete on equal terms with the Republican Artillery. [See Report Royal Commission, p. 91. On p. 92 the Commission says that the War Office were unable to devise a good quick-firing gun, but during the War purchased from German makers "real" quick-firing guns, and used them as a model.] These facts are mentioned to indicate that a life devoted to ceremonial and playing at fighting will ruin any fabric, and that medical and veterinary officers can never feel too profoundly grateful that their training does not consist in "playing at doctoring." The stern reality "keeps their hands in," and daily trains their judgment; this is the reason why, if given a proper organisation, no excuses for failure on Service should be admitted. The fate of the Departments of the Army lies largely in the hands of those who are demonstrably unable to look after their organisation and technical requirements, or to keep abreast of modern discovery and invention.

Commission, Appendix 52, p.354, says that he does not consider it advisable to rug M.I. ponies, it renders them liable to chill. Nor does he advise clipping unless the coat is in such a condition that it cannot be cleaned.

I entirely agree with Colonel Haig in the remarks he makes, referred to at p.237, on the pampering of troop horses. It is not the weather which kills horses, but starvation and overwork. No troop horse in health should ever know the feel of a blanket; he is born clothed, and his early life spent in the open, exposed to the elements without cover, did not kill him nor could it. If a blanket is essential, why not a hood? If there is one part on which a horse hates rain it is his face. Bandages will next be required?

Reams of official correspondence exist on the question of blankets, but no one in authority has taken up an infinitely more important and practical question—that of nosebags. The present pattern of nosebag, used in civil and military life, is a disgrace to our inventive genius, it is merely a vehicle for wasting a quarter of the food. The army nosebag is still worse, as it has been sacrificed to appearance. It is infinitely too small, of the wrong shape, fragile where strength is required, and in consequence lasts but a short time. We complain of short rations, but never of the waste-producing, leaky, dirty contrivance in which they are placed for consumption. It would be a sound measure of economy for the Secretary of State to offer a prize of £1000 for a practical method of feeding horses without a manger, and without waste. Think of the trouble and expense of carrying forage immense distances, to be wasted on the ground when it has reached the horses for which it is intended! The questions of nosebags and picketing are two of the three most pressing necessities for horses in war, compared with which blankets are a trifle and a luxury.

#### ACCLIMATISATION.

When men and horses are sent abroad to fight there is no time to wait until they are acclimatised. Nevertheless, in the case of the horses sent to South Africa, more than that of the men, acclimatisation was an important physiological process, for the animals landed either with a winter coat in an African midsummer, or a summer coat in winter; apart from all other considerations a physiological re-arrangement on this account had to be made. It was notorious that many of the horses landed, even before Christmas, refused to change their coats for several weeks. The mutation of the coat as a seasonal adjustment is not everything; the digestive functions of the horse are notoriously delicate, in spite of a certain ignorant saying to the contrary. A sudden change of food, corn or fodder, is a most disturbing element to his interior. A new grain suddenly introduced cannot be digested, and when horses refuse it and prefer starvation, they

are exhibiting a protective instinct. A change in grain may lead to laminitis and other troubles due to causes we need not here consider, while a change in herbage may be followed by considerable gastrointestinal disorders. Even the horse of South Africa will not tolerate a sudden change of pasture, as we have seen at p.202, and only the "karoo" pony can utilize the bush which is so irritating to a new comer. A change in water is probably more insidious in its effects. A good deal of the water in parts of South Africa is brackish and that from wells frequently very hard; both storage and river water suffers under the effects of being churned up in the process of watering, by which a large amount of mud in suspension is swallowed. To animals which have been previously consuming water of unimpeachable purity, such changes as these must create not only intestinal irritation, but alterations in the physiological process of urine-secretion.

Life in the open is the natural existence for all domesticated animals, but circumstances not connected with health, as many think, demand stabling for comfort. The stabled and pampered troop horse\* found himself in South Africa suddenly exposed to scorching sun by day and drenching dews by night. His long English winter coat was burned brown or came away in patches, and was clogged with sweat and dirt. His rest on ship-board had robbed him of such muscular fitness as he possessed, and he sweated and groaned under his 20-stone load. We made no concessions to him on account of these matters, though he was a stranger in the land. He was turned out to graze but did not know the meaning of it,† and abused his freedom by stampeding. Prevented from stampeding by knee-haltering, applied by equally ignorant men, his leg was cut or the limb otherwise damaged. He shivered and shrunk up in the rain, and the absence of generous feeding, hay and water, soon left him a shadow of his former self.

A difference of opinion exists as to the length of time it takes for an animal to acclimatise in South Africa. By some two months was considered sufficient,\*\* but it may be safely stated that in the case of the horse a year is not too long a time, until, as Colonel Blenkinsop originally pointed out, the animal has learned to change his coat correctly. Men are very much inclined to measure horses by themselves; a horse is a far more delicate animal, and much more readily upset and killed. Assuming a year to be none too long for the important changes indicated above to occur, we may say that very few horses lived long enough in the war to be physiologically acclimatised. Among the causes,

\* Haig ("R.C. Evid.", p. 404, Vol. ii.) says: "Hitherto there has been too much pampering in peace time."

† See pp.14, 29.

\*\* General Butler believed that at least two months were required to get used to the conditions of water, food, and altitude, and that four to six months were preferable. See Q. 5304, "C. of E. Rem. Evid.", p.174.

then, contributing to inefficiency was this one of want of acclimatisation.

The question, however, is whether it would not be possible during peace to render animals less susceptible of exposure and hardship when taking the Field? We firmly believe this to be the case, and would indicate as one measure the system of feeding on a mixture of grain rather than exclusively on one, as not only being more economical during peace, but preparing the way for the varieties of grain rations met with in war.

The softening of fibre resulting from pampering should be eradicated. No troop horse should wear a blanket so long as he is in health. No troop horse should be clipped all over. Sufficient hair may be taken off the belly, brisket, thighs and arms to counteract sweating and facilitate grooming, and yet without necessitating the use of blankets. There is no occasion for troop horses to resemble in appearance the artificial product of our hunting and racing stables. He is neither hunter nor race-horse, or he would never have found his way into the ranks. He should be the natural product of common-sense management, and not the residue of an artificial and unnatural life. His stable should only mean protection from rain and wind, such as he endeavours to provide for himself when living freely in the open; here he gets under a hedge. There should be no windows capable of shutting, no doors capable of closing, no light which can be cut out, no reeking putrifying "Continental system" of bedding to soften and destroy the horn of the feet, and by fermentation to produce sufficient heat to raise sensibly the temperature of the building. There should be but one or two degrees difference in temperature between the air of the troop-stable and the outside air, bearing in mind that the sole object of the stable is not to provide an oven for the animals to live in, but shelter from wind and rain. From this it must not be supposed that either wind or rain kill well-fed horses living in the open; it has no effect excepting that of making them look utterly miserable. If wet weather continues animals lose condition from the utter inability of feeding them properly, the material is blown away or trampled in the mud. Stabling is therefore economical, it is also sanitary, for bodies of horses cannot be kept standing constantly on the same ground, but it is not an essential to well-being, and the temptation to convert it into a house should be resisted in every way. Common-sense must be invoked in order to avoid the temperature feelings of animals born permanently clothed, being confused with those of the animal born naked.

We do not ask that Army horses should live in time of peace under conditions resembling a campaign, but that the system of protection should be Spartan in its simplicity, and every endeavour made to render their buildings as much as possible like the open air, without its drawbacks. The feeding in peace time is defective because, as we have seen, we feed on one kind of grain only; better feeding would be obtained for the money now spent by

using a mixture of grains, the advantage of which to the troop horse has been previously referred to.

A remarkable degree of body-delicacy results from pampering: perhaps it receives its highest expression in the dog. The moment man brings animals under his care he is inclined to fashion their lives on that of his own, which, in the main, is a perpetual striving after comfort.\*

The effect of sudden change of altitude on animals is not known. Probably, for altitudes up to 5000 feet, the actual reduction in atmospheric pressure is rapidly compensated. Altitude, it seems to us, is less a source of trouble *per se* than its concomitants. The lowered temperature, for instance, may be more important than the reduced pressure, but doubtless the different vegetation found at various levels is a far more serious cause of difficulty to the herbivora than either the temperature or pressure. At very high elevations there is a difficulty in breathing owing to a reduction in the oxygen content, but no such altitudes as these were met with during the war.

#### FARRIERS AND SHOEING.

Had South Africa been a country where the wear and tear of shoes was considerable, nothing would have prevented an entire collapse of the military arrangements within three months from the date of taking the Field. The fates treated us kindly in this matter; there were no metalled roads, there was plenty of soft going, a veldt which polished the shoes like silver, and no serious rain until Bloemfontein was in sight. It is true there is a good deal of rocky ground in places, but it is short lived and mere outcrops; stones and boulders abounded almost everywhere, but these do not wear shoes out, though they tear them off, and may bring tired horses down. The fact is that shoes which last barely a month at home during the idleness of winter, lasted three months in South Africa, and often remained on until they dropped off.

The explanation of this latter fact was the paucity of the staff of farriers with the Army, or more correctly, the bad system under which this staff was employed. Shoeing in our Army has been carried out by a regimental system as long as mounted troops have existed. Over a hundred years ago the farrier was not only the shoer of horses but the veterinary practitioner. He acted as such so badly that in 1796 it was determined to replace him by a properly trained man, and from that day onwards he has been the technical assistant to the latter, and the shoer of horses. He is a regimental man, holding first an appointment as shoeing-smith, and if promoted receives rank. He has nothing to do with horses outside those of his own regiment, nor can he be employed to do anything for an animal the property of the public not belong-

\* In connection with this the remarks on p. 239, dealing with blankets, may be consulted.

ing to his own unit without the approval of his Commanding Officer.

When mobilization occurred every regiment of Cavalry had three Sergeant-Farriers, and eighteen Shoeing-smiths. Every Battery one Sergeant-Farrier and three or four Shoeing-smiths, dependant upon whether R.H.A. or R.A. These men were not only craftsmen but soldiers; they took their place in the ranks as such, and carried out their technical duties afterwards. In the Artillery and Army Service Corps they are not only shoers of horses and assistants to the Veterinary officer, but also Carriage-smiths. Each Farrier and Shoeing-smith, therefore, performs the duties of two men, soldiers in the Field and tradesmen in bivouac. Each should have, as fortunately most of them possess, an iron constitution, for he has twice as much work to perform as any other man in the British Army, and he has attempted to carry out this double function with a loyalty and devotion beyond praise.

It is fortunate, however, that the wear of shoes in South Africa was light, or it would have been impossible for the staff, as organised, to have carried out the shoeing. No man can be in the presence of the enemy, or marching, all day and shoeing all night. This is what we mean in the opening statement of this section—that had the Army been dependent upon shoeing for its movements, a breakdown would have occurred in less than three months.\*

The proportion of Farriers and Shoeing-Smiths to horses during peace is in excess of requirements; this is due to the fact that these men are counted as soldiers in the ranks. If their numbers in the ranks were reduced, the State would have to sanction others to take their place. From a regimental point of view no reduction is therefore possible. In war the numbers are sufficient for the purpose for which these men are engaged, provided that they are not otherwise employed. It can be seen from what has been stated above that the Farriery Staff is overworked, and that the duties assigned to it are always largely in excess of that of the other members of the rank and file. In addition to being soldiers and farriers, they are, as we have seen, charged with a third function, *i.e.*, in subordinate charge of the sick horses of their units under the veterinary officer.

This brings to light one of the many difficulties of their position; they have to serve two masters, the battery or squadron Commander, and the veterinary officer attached to the unit. It is astonishing the loyalty they show to both, even when aware of the differences of opinion which at times arise between the unit Commander and the veterinary officer in connection with the care of horses.

Another and distinct group of artificers concerned in the horse-shoeing question, are the hastily

trained "cold shoers" of units; these are men who have been induced by a premium to qualify to nail on a shoe which they are practically unable to fit. Their number per unit is a variable quantity, and depends generally upon the interest taken in their training by the unit Commander. There may be many or few. They leave the forge after a few weeks' instruction, and their chief use is to replace shoes in the field, especially in Cavalry when the squadron is working in detached portions. These men have their marked limitations, but are useful under pressure of work. They are never employed when better qualified assistance is at hand, and once they have left the forge their subsequent connection with it is purely nominal.

When an army passes from a peace to a war footing the number of animals with units is increased, and in addition units are created which have no peace representation, or but little. For these no farriery service exists. The account given in these pages of the events of the war will best illustrate the case. A transport was created consisting of thousands of mules: for the shoeing of these animals only the small number of men with the transport on a peace footing were available. Regiments of Mounted Infantry were created, and thousands of animals brought into the service; for the shoeing of these not a single man existed, excepting the few trained in peace as cold shoers of regimental Infantry-transport. Scores of irregular regiments were created with hardly a trained farrier amongst the whole number, and to these may be added remounts by tens of thousands, for the shoeing of which no provision existed. We have referred at p. 21 to the difficulties existing at the outset of the campaign in providing farriers for irregular regiments. That the local knowledge of some of the Commanders of these enabled them to know where to recruit farriers is undoubted, but that this never met the whole trouble is equally certain. Fortunately the colonial animal ridden by these men rarely requires shoeing behind, which reduced the amount of work by half. At the early part of the war some army farriers were lent to the first regiments raised, but this was only a part of the general policy of robbing Peter to pay Paul, for these men were required with their regiments. The Colonial Commanders were exasperated by being informed that they must make their own arrangements for shoeing, as if the material, possessing all the needful qualifications, were always on the spot and only needed to be embodied.

The losses among Farriers and Shoeing-Smiths in the Field are difficult to obtain separately, as they are mixed up with those of the rank and file, but early in the war a Cavalry Brigade lost in three months nearly 33% of its shoeing staff, and two Cavalry Regiments and a battery of Horse Artillery lost over 43% in six months. The total number of men in these two groups rendered inefficient was 39, of which:

2 Died,	10 Sick,	4 Wounded,
4 Captured,	19 Invalided.	

\* Colonel Haig, the Adjutant-General of the Cavalry Division, in his evidence before the Royal Commission, Q. 19,299, p. 403, stated that many horses were left unshod from the day they embarked, and that time and men were lacking to shoe remounts before marching.

The general wastage of men per annum during war is calculated at 60% for Infantry, 50% for Cavalry, and 40% for Artillery.\* The groups of Farriers, etc., quoted above, are too small to enable the facts of the general loss to be stated in positively definite terms, but there can be no shadow of doubt that the wear and tear amongst this class of soldier is higher than in any other branch, and the reasons for this have already been stated.

The remedy is simple. Farriers and Shoeing-Smiths should be kept wholly for technical duties, and should not be included among the fighting numbers. Their place should be with the transport, in order to be kept as fresh as possible for the work which awaits them in the next bivouac. With such a scheme fewer men could do the work. If a man shoes an average of four horses a day with machine made shoes requiring little alteration, he may be regarded as having earned his pay and keep. On such a basis six men could easily keep a regiment of Cavalry shod.

The staff of Farriers and others maintained during peace and war has no definite basis; in Cavalry it averages 28 horses per man per month in peace, and 26 in war. In the Artillery the proportion is reversed; in Horse Artillery, during peace, 27 horses per man per month, and during war 46; Field Artillery 22 during peace, and 36 during war. The proposal above made admits of a man shoeing from 90 to 120 horses a month, but for safety it is best to take the lower figure. If the squadron be taken at 150 strong in peace and 160 strong in war, two men should be able to keep these horses shod. At present, for this purpose the staff is five in peace, and seven in war. The proportion of Farriers taken into the Field must always provide against accident, disease and pressure of work. A shoeing staff of three men per squadron should leave a margin to meet all difficulties (see p. 243), provided they are taken care of instead of being worn out by overwork and exposure. No other soldier in the army has, on returning from the Field, to take off his coat, after a long tiring day, and begin the job for which he has been trained, while his comrades are resting and sleeping. The scheme of reducing the shoeing staff and putting it with the transport is economically sound.†

There ought to be a Corps of Farriers administered by the Army Ordnance Department, in the same way that it administers the Corps of Armourers. These men should be for shoeing only,

\* See R.C. Evid., Q, 4453.

† Colonel The Marquis of Tullibardine stated before the Royal Commission that he considered the lives of the Farriers of the Scottish Horse to be too valuable to place these men in the fighting line, so that as far as possible he kept them out of it. He pooled the whole of his shoeing staff, and under the Farrier Major these men carried out the shoeing not by squadrons, but regimentally. In this way the work was equally divided. It was no question of whether a horse belonged to the man's squadron or not. This excellent practice might have been adopted by other regiments, and the equitable distribution of work and saving of Farriers assured.

and not mixed up with the dressing and treatment of the sick. They should be posted to regiments for duty, but not to belong to it. They should be under the orders of the Squadron Commander, for he alone is responsible for his horses. For emergency work in the Field the regimental cold shoer should continue to be trained as at present.

Another point that needs consideration is the formation of a Reserve of Farriers. There is practically no such thing in existence. One should be formed, not only to meet the wear and tear of service in the Field, but to provide for those units which only exist or are created during war.\*

With the Cavalry Division under Lord Roberts on the Modder River there were not less than 200 Farriers and Shoeing-smiths, yet not one of these men could be detailed to shoe M.I., Transport or Remount animals. These had to go without shoeing. Such a state of affairs could not continue indefinitely; the engagement of civil farriers was at first hinted, and by 11th April, 1900, a reality. A few men were at first engaged, but they did little towards lessening the mass of neglect in shoeing. They were engaged at a rate of pay which would have turned the head of an infantry subaltern. They received at first 10/-, and later 12/- a day pay with rations and quarters, and were engaged for three months. They were of all classes—Jews and Gentiles, Poles and Dutchmen; where they all came from was remarkable, and though there was little means of testing them before engagement, there were very few downright failures among them, though there were very many weak vessels. At first these men were kept in standing camp, later on many of them volunteered to accompany the troops, and remained for months in the Field. Some hundreds of civil Farriers were thus employed from time to time; by June, 1901, there were 100 working for Remounts alone,† and by the 31st May, 1902, the number of civil Farriers with the Remount Department had reached 175.‡ The numbers with hospitals and columns are not known, but certainly not less than another 200. The increase in numbers followed as the strength of the army in horses was increased, and as the military Farrier and Shoeing-Smith gradually disappeared.

Anything more expensive than this system it would be hard to imagine,‖ furthermore, it filled the Army Farriers with discontent to see a civilian earning a rate of wage in one day that he could barely get in a week.

\* On one occasion it took 74 telegrams to obtain the services of a Farrier for a Mounted Infantry Regiment, and there were scores of cases where no record of correspondence is available.

† There were in addition, at this time, 35 Army Farriers and 60 Indian Farriers with this Department.

‡ On the 31st May, 1902, there were, besides the civilians mentioned above, 60 Army Farriers and Shoeing-smiths, and 104 Indian Shoeing-smiths.

‖ At one Remount Depot the Commanding Officer paid the civil Farriers by piece-work as being economical. It resulted in these men netting £42 a month a head!

A partial remedy for this state of affairs was provided by the War Office sending out "specially enlisted" Farriers from home. These men wore Artillery uniform and were at first claimed by this arm; after great delay they were distributed. They soon found out that the civilian of the country was receiving 10/- or 12/- a day, and so started by being discontented. Their pay was 2/9 a day with a bounty, and they were engaged for a year. At the end of January, 1901, there were 45 of these men at Cape Town, time expired, awaiting passage home, and not one could be employed even on temporary duty. The fault lay with the terms of their contract, which should have been "for the campaign," and not "for a year."

The shoeing of the horses in South Africa finally resolved itself into shoeing by the Remount Department. Every animal, during the last eighteen months of the war, was shod all round by Remounts before issue, and this shoeing largely covered the period of the animal's utility until returned to Remounts for rest and repair. Towards the end of the war the Remount Department shod at the rate of 35,000 animals per month.\*

From what has been stated it is clear that the Farriery system of the army broke down immediately it was tested under active service conditions, and every officer of sufficient experience in the Veterinary Service knew this to be inevitable. Comments on Farriery organisation have appeared in nearly every veterinary report on a campaign, but no notice was taken of them, nor indeed, in spite of the collapse in South Africa, have any steps been taken to remedy the state of affairs above described.† A Farriery organisation on a regimental basis is bound to fail unless a very large reserve is obtainable on the outbreak of hostilities.

The material for shoeing was generally ample in quantity though not in quality. It is true there were innumerable complaints of a shortage or absence of shoes when columns came into the line to refit, but this was generally due to the delay in transit or the uncertainty in the movements of columns. The stores including shoes went to one place, the column to another. The complaints of ill-assorted sizes were more reasonable. Large horse shoes were sent for small horses, and even the largest size of draught hind shoes found its way into Ordnance Depots, having previously occupied valuable space in vessels and railway trucks, to be left finally on the hands of the Ordnance Department.

\* These figures are important. The total shoeing staff amounted to 389 men, and without making allowance for any of these being sick, the average number of horses shod per month amounted to 103 per head.

Our estimate on p. 242, of three men per squadron in the Field for the shoeing of 160 horses a month, is therefore, liberal, though not in excess of requirements, as many animals will require shoeing oftener than once a month.

† The Royal Commission did not enquire into the breakdown of the Farrier organization, though in Q. 1783 the matter is referred to. This could never have occurred had the "horse" interest been represented on the Commission.

No one wanted anything but small shoes. Even the small size of English shoes was unnecessarily heavy, so shoes came from India. Before the war broke out the Ordnance Authorities at Cape Town had been advised by the Veterinary Service that the shoe which was most suitable for the country was that known as the Egyptian pattern. This was a shoe evolved by the Veterinary Authorities in Egypt as the result of experience; it was light but gave good cover, and so made as to assist a tired horse, or one with defective action. These were not stocked as suggested, nor were any obtainable until long after the war started. The shoes generally supplied were machine made, but the stock had run so low that the Government bought shoes anywhere and everywhere, many of these were hand made and disgraceful. In addition, they were all without clips, and clips cannot be drawn on service, as no fires are carried.

This is what the Director-General of Ordnance at the War Office said to the Commander-in-Chief on the matter of the Reserve of Horse Shoes, a few weeks after the war broke out:

"Our reserve of general shoes was utterly inadequate to meet the demand. We have had to buy in the market whatever we could get. As an example, we had an authorised reserve of 52,000 sets of horse shoes, and no mule shoes. I have to send 35,000 sets of horse shoes and 40,000 sets of mule shoes to Africa monthly to keep the animals shod. I have to go to Germany and Sweden for horse shoes, and to the United States for mule shoes."—"R.C. Report, App: E," p. 279.

We learn in this statement the astounding fact that no reserve of mule shoes was maintained, though every successive Government for years past had known that on mobilisation for service abroad mule transport would be employed. It would be interesting to know what became of the 40,000 sets of mule shoes sent monthly to South Africa. They were certainly not put on the feet, for the animals worked without shoes, as there was no one to shoe them. The wonder becomes all the greater when we learn from the R.C. Evid., Q. 1603, that the issue of horse shoes later on grew to 100,000 sets and of mule shoes to 70,000 sets *monthly*.<sup>o</sup>

A large proportion of the nails were bad. Their shape invited them to break at the neck, and that the material also was bad was shown by the fact that frequently all the nails would break and the shoes drop off. No doubt the stock of nails, as well as of shoes, was insufficient to meet demands, and nails of all patterns and makes were purchased. It was amongst these that the failures occurred, for the regulation nail was a good one.

The condition of feet which had been carrying shoes for weeks without being removed is easy to imagine. The labour involved in their reduction to normal length was considerable, and rasps were not plentiful. An ingenious horn cutting pincers was introduced by Major Blenkinsop, which rapidly removed the over growth, and left a surface readily

\* The whole track of the Army was mapped out by dead horses, cast shoes, wasted oats, and rifle ammunition.

levelled by the rasp. Though a labour-saving machine it was something new, and was disliked by the very men who should have welcomed its appearance. It is to be hoped that it will take the important place it deserves in our next campaign, for the supply of new rasps can never be sufficient, and the saving of time in shoeing is an all-important matter.

The injuries resulting from shoeing and neglect in shoeing may be briefly dealt with.

The condition of the feet of animals arriving at hospital was almost beyond belief. They were overgrown, deformed, held the broken shanks of nails and portions of shoes, and contained in any cleft or space stones and mud, baked to a clay by the heat of the foot and the ground. This concrete-like mass required considerable effort to dislodge. If a portion of shoe was found on the foot it was embedded into the seat of corn. Suppurative diseases of the feet were in consequence appallingly common; soles were under-run, and fistulae of the coronet became a large and serious class of surgical cases, the number of which is beyond belief.

Never again, let us hope, will an army have so large a number of quitters to deal with. Not only did they arise from neglect in shoeing and untended injuries caused by nails, but also from damage to the coronets inflicted when horses are in mobs, or crowded together. We can hardly think that any surgical trouble in our hospitals gave such bad results in treatment as the quitter cases, due to the exceptional difficulties these always present, and the impossibility, with untrained assistants, of daily dressing large numbers. The introduction of "stocks" into hospitals was helpful in this and similar surgical cases, but it can never be said that our quitter work was satisfactory.

Something perhaps should be said of cold shoeing in the Field, for the reason that its advantages are not even now fully accepted. It is a makeshift system, but absolutely essential in war. It offers no serious difficulties with the lighter class of shoe, but is impossible with the heavy shoes. A large mass of iron cannot be dealt with without fire and anvil, and rightly neither exist. Hot shoeing in the Field is an absurdity; where is the needful fuel to be carried, or even obtained; further, the forge is always the first thing dropped by the way when horses run short; this is invariable.

The principle underlying cold shoeing is that the size of shoe nearest that of the foot must be selected. Small alterations of increase or decrease of width are possible with light shoes, and it even ought not to be beyond the range of mechanical skill to devise a machine for making alterations in width of the heavier class of shoe, but more than that must not be expected. So long as the rim of iron enables a horse to take his place in the ranks we must be content with rough fitting. In spite of the fact that one-and-a-half millions of horse-shoes

were sent to South Africa during the war, it cannot be said that "cold shoeing" was either properly tested or proved successful, for the reason that the Farriery system on which it depended broke down, and the feet had to take care of themselves. The loss which resulted from this neglect is incalculable.

The carriage of horse-shoes in the Field is divided between the horse and the transport waggons. As every ounce of unnecessary weight will, in future, have to be removed from the horse's back, it is clear that the shoe case with fore and hind shoe at present hung on the saddle will have to disappear. A few shoes carried by the various "cold shoers" are sufficient to meet urgent demands in the Field, all others will have to be carried on wheels, and accompany the transport.

To provide an efficient Farriery service, the first essential is that the regimental basis must be abolished and a Corps of Farriers created; the shoeing must be Army and not regimental. The men must primarily be tradesmen and not fighting soldiers; they must be taken care of by moving with the transport, for without doubt they are the most valuable artificers who take the Field.

A Corps of Farriers would enable a General to send tradesmen wherever they are required; it would provide for the troops in the Field, for emergency corps, Remount depots and veterinary hospitals. It should be a single organisation, under central control so far as the distribution of the men is concerned, though, for discipline, under the officer commanding the unit to which the men are attached. The whole time of the Farriery Service during peace or war must be devoted to the care and attention of the horses' feet. No parades, drills, or military operations after the indispensable primary training has been completed. Emergency shoeing in the fighting line must be carried out by the regimental cold shoers, trained as at present, and in receipt of a special rate of pay to encourage men to qualify. The part hitherto played by Farriers of Regiments as veterinary assistants to be taken over by the personnel of the Army Veterinary Corps.

The Royal Commission on the War mentioned the Farriery question. In Q. 1783 the following was asked the Director-General of Ordnance: "You may have seen the accusation that there were practically no farriers in South Africa. Which department would deal with that?—A. The supply of farriers would be in the Adjutant-General's department."

Unfortunately, the matter subsequently appears to have been lost sight of, for no evidence was given on the point.

### SORE BACKS.

Sore backs appear inseparable from mounted service, they have existed as long as the horse has been used in war. It was reasonable, however, to suppose that, as knowledge advanced, a reduction in this class of injury should have been possible, and that during the centuries a standing army has existed, sufficient experience would have been gained to enable us to pronounce definitely on any given type of saddle as good, and adopt it, or any type as bad, and avoid it.

If we wish to gain a true insight into the sore back question we must go back to the forty years of peace succeeding Waterloo, during which period all the lessons of war appear to have been forgotten. At the end of this time it had become established as a cardinal principle that sore backs arose from the careless manner in which the man saddled or rode his horse, and the rider was accordingly punished. The necessary corollary of such injustice was the concealment of injury. The Cavalry in the Crimean Campaign suffered severely from this class of wound, but the wholesale destruction of the mounted forces by starvation withdrew attention from the sore-back trials, and after the war—as after all wars with us—the inconvenient question was never taken up, and in a few short years the matter was apparently forgotten.

The Zulu War and, immediately after, the Campaign in Egypt, once more brought the matter to the front; for no sooner were mounted troops compelled to act under service conditions than the old bane of Cavalry reappeared. It is fortunate that at this time—the early eighties—the Cavalry had as their Inspector both a soldier and a Veterinary Surgeon. The late General Sir F. FitzWygram established a crusade against the then pattern of saddle, studied the question of sore backs, showed that the saddle was more often to blame than the man, and was instrumental in introducing saddles with iron instead of wooden arches into the service. Above all, he provoked an interest in a subject about which, strange to say, extraordinary ignorance existed. His official position insured that the question received attention, and he broke the first ground in this all-important matter. Reforms cannot be produced in a day, and it is doubtful whether among the older Officers of Cavalry at the time any enthusiasm in the subject existed.

It was evident that the saddle could not be studied apart from the horse, and there was still a great deal connected with the latter which required elucidation. Both the theory and practice of saddle fitting was necessary, and this could only be correctly arrived at by a knowledge of anatomy and physiology. The Veterinary service took the matter in hand, and one of its number, after some years of work, produced a *Manual of Saddles and Sore Backs*, in which, for the first time, the grammar of the entire question was laid down. This Manual aimed at giving exactitude to what was previously

conjecture and guess work; it swept away some of the then existing fetishes, and reduced the question of saddle fitting to science and common sense. It promised no more than it was capable of demonstrating could be achieved, and the success which attended the application of its principles and practice secured the attention of all interested in the welfare of the horses. But enthusiasts in the question were not numerous. The whole matter appeared, like a revealed trick, so absurdly simple, that few doubted their ability to put it into practice when the time arrived. The sermon was over and over again preached that each case of sore back was a problem in itself, and that nothing but long practice could secure the skill necessary in dealing with the many sources of injury to which this part is exposed. Nevertheless, good seed was sown, for the general trend of events was in the right direction; the Cavalry had been taught the make and shape of a horse's back, the physiological conditions under which the back carried weight placed on an unyielding machine, and the causes of injury, with a definiteness and exactitude unknown to the previous generation. Ten years later, which takes us up to the middle of the nineties, it is fair to assume the majority of Cavalry Officers knew something of this all-important matter, though the opportunities for practice were confined almost entirely to the manoeuvre season.

Side by side with these changes there was an ever-increasing desire for alteration in equipment; the type of metal arch underwent many changes, some unimportant, some necessary in consequence of proved defects. Other changes were radical and opposed to experience. One of the worst was introduced shortly before war broke out; the burden of this story is to show that it was responsible for a very great deal of the trouble which subsequently occurred.

It must always be borne in mind that no test of equipment in peace is ever carried out under conditions approaching those of active service, so that the root of the matter is rarely arrived at.\* Nor are the tests imposed such as might be expected when important changes in equipment are under consideration. Take the case of a change in the type of saddle. The test usually employed is to issue half a dozen or so to a few selected regiments and order a report to be furnished by a given date, probably far too short a period for any real test to be employed. The saddles arrive, and those responsible for carrying out the observations are, perhaps, not even taken into the confidence of the authorities as to the objects aimed at. The usual conflicting reports go in from the various regiments, some destructive, some constructive, and a man sitting in an office miles away has finally to decide the matter on the data before him. Is it any wonder

\* A good example of this was the canvas bandolier for carrying ammunition in the Cavalry, and the pouches in the Infantry, which in each case allowed the ammunition to fall out as the man lay on the ground, and so kept the enemy well supplied.

under these circumstances that blunders arise? \* No question of horse equipment should be decided without an experiment on a large scale, carried out under conditions as nearly approaching those of active service as is possible. Confining ourselves entirely to horse equipment, no saddle, no shoe, nosebag or picketing gear should be adopted that has not been used on a whole regiment which has marched with service weight at least 400, and preferably, 600 miles. Day by day the test should become more rigid and exacting, and in the case of saddles, the animals should even, at one period, be placed on reduced rations, in order that the effect of loss of condition may be studied. In no other way than the above is it possible to get at the root of matters; anything based on what may be termed barrack square tests is worthless. A type of saddle or shoe which comes successfully through such a test as we have suggested is not likely to have much wrong with it. All the weak points having been revealed, the matter is then in a condition for vigorous handling. Of course, the objection against a proper practical test centres around cost, but is it cheaper to order imperfectly tested equipment, than pay the necessary price for rigid inquiry? The curious will be interested to study the patterns and changes in saddlery which have taken place within the last thirty years; such may be culled from the "List of Changes in War Material," and other official sources.

We are now in a better position to understand the condition of the saddle question before the war. In about twenty years we had passed from wooden arch saddles with hair panels, to saddles with a metal arch and hair panels. The vicissitudes of the metal arch saddle we have previously hinted at. A "Saddlery Committee" sat for years, and evolved type after type. Of wrong pattern and material to start with, these arches proved prolific sources of in-

\* Following the custom adopted in this history of quoting authorities or giving examples, we will take one or two connected with the question under notice.

When the iron arch saddles were introduced after preliminary trial and favourably reported upon, it was found, after the whole army had been equipped with them, that the front arch was so weak, that the saddle came down on the withers. As a matter of fact the arch could be opened or closed by hand! A strengthening plate was put in. This was applied to the thousands of saddles in use, and was found ineffective. Steel arches were then tried, and finally a steel angle iron arch was adopted. We submit that the weakness of a flat iron arch could have been discovered in the preliminary experiments had these been of a searching character.

Several years later, to take another example, for some reason no one understood, the seat of the saddle was split in the centre from end to end. It is assumed that the split was well reported upon. When generally adopted it was found that the saddle blanket worked up through it and galled the man, the result being that all the seats had to be closed. It seems very obvious that this fault should have been capable of being found out before saddle seats were ruined by splitting, and heavy expense incurred in restoring them.

Other examples might be quoted, but the above suffice to support the argument we have advanced for searching and extensive tests of new equipment before adoption.

jury; modified and strengthened as years rolled by, a type was in course of years arrived at capable of withstanding the enormous strain imposed on a soldier's saddle. The parallel bars on which these arches rest were then attacked, but not until after years of representation from the Veterinary Service that their great length impeded the horse's movements by pressing on the blade bones. In the course of these alterations the old hair panel was taken away and strips of felt employed together with a small blanket placed under the saddle, to take the place of the hair panels. There were other alterations projected, such as a self-adjusting side-bar, but this matter we need not here enter into, as it never crystallised. *The war caught us after all hair panels for army saddles had been withdrawn, and nothing but a thin felt panel and indifferent blanket substituted.*

Before proceeding further we must look at the hair panel. It was an elastic bag secured to the parallel side bars, and was capable of taking the impression of a horse's back almost as completely as if made in wax. The hair shifted sufficiently in the panel to adjust the distribution of weight, while its elastic motion between the saddle and the back was an obvious advantage. It had its drawbacks; in course of time it became lumpy from the penetration of sweat, it became compressed and thin, and the white flannel cover necessitated pipe-clay in order to improve its appearance. Every application of wet pipe-clay helped to render the hair within lumpy, and the beating together of the panels to remove the surplus material destroyed the exact impression of the horse's shape which the panel had received, and moreover, bunched the hair into definite parts of the panel, instead of leaving it equably distributed. But the panel possessed advantages of the most pronounced character; extra material could be introduced into it in a few minutes, so that the condition a horse was losing in the muscles of the back could be artificially replaced in the panel, which thus ensured the saddle being kept at its proper height above the vertebrae; further, the panel could be "chambered" over a sore or weak point, and the pressure removed. These were advantages of enormous importance, and those responsible for stripping the saddles of their hair panels and replacing them by a piece of felt—which became as hard as a board through sweat—and a thin folded blanket, could never have appreciated their advantages or gauged the horse's requirements. A saddle tree with only a blanket and felt cloth (numnah) beneath it requires far more careful adjustment than one with hair panels. It is quite true that the blanket possesses some advantages denied the hair panel, but *what was required on a campaign were both hair panels and a blanket*, the function of the latter being to replace back waste by different methods of folding.

It must not be thought that the question can be disposed of in the simple manner the last statement appears to indicate. It is not only a large subject, but confused by infinite detail, due to the

fact that no two horse's backs are exactly alike. All that has here been attempted is to give a brief history of the matter, and so enable us to understand the condition of affairs when the Campaign opened.

The whole of our mounted troops took the Field with a type of saddle quite fit for peace conditions, but absolutely unsuitable for war. It did not require any very great sagacity to forecast what must occur to horses' backs under the circumstances.

This prepares us for the statement that sore backs represented one of the chief causes of inefficiency among the horses in South Africa, only exceeded by debility and mange. They were the first troubles to arise, and lasted throughout the whole campaign. Let us at once say that sore backs are caused, not only by defects in the type of saddle, but defects in fitting and workmanship, defects in horse-management, underfeeding, bad horsemanship, crushing weights, long hours of work, and softness of condition. It is obvious that all these causes may overlap.

It is astonishing to learn from the Director-General of Ordnance, R.C. Report, Appendix E, p. 278, that at the opening of the Campaign in South Africa, there were only 500 saddles in reserve, to meet the wear and tear of the 16,000 sets in possession of the troops on 15th Dec., 1899. On the same day there were 500 saddles in reserve for Mounted Infantry, and already a demand from South Africa had arrived for 11,500 sets.\* The trade could not supply, and the order went to America. We are not concerned with the question of stock in hand, dreadful revelation as it is, but it is evident that material like saddlery ordered in a panic is liable not only to fail from hasty workmanship, but must necessarily lead to the introduction of new patterns, when, as in this case, the entire stock of foreign manufacturers is bought up regardless of type or suitability.

There were many types of saddle in use during the war, derived from outside sources, which all differed in essential points from that employed by the Regular Forces. The United States, India, South Africa and Australia, all furnished saddles which generally possessed one point in common, inasmuch as they were lighter than the home patterns, and, excepting those of the United States, possessed stuffed panels.

The first great division of types of saddle employed is into panel and non-panel. The non-panel type is represented by the War Office pattern, and those made to this pattern, whether at home or abroad, after war broke out. Another non-panel

\* In this communication we are also told that there had been 500 single sets of horse harness in store, but that already 800 sets had been sent to Africa to replace casualties. There were only 1700 mule sets of single harness maintained, though 33,000 mules were known to be required for transport purposes on mobilization. The reserve of picketing pegs, ropes and mallets, was not sufficient to supply, even at this early date, one-fiftieth of the demands from South Africa.

saddle was the United States Cavalry pattern, the issue of which at Pretoria is referred to on p. 82.

The second group is that of saddles with panels, and is typified by the Colonial semi-military pattern employed by the Staff and Officers of M. Infantry, and the Colonial pattern pure and simple, with nothing military about it. In the non-panel type, the bare tree is placed upon a folded blanket beneath which is a numnah (a cloth of felt). In the panel type, the tree is covered by a panel stuffed with horse hair and flock, and resting either directly on the back, or on a numnah or blanket. In the Colonial semi-military pattern the panels are readily get-at-able, so that their removal from the tree is a matter of a few moments; in some others of the Colonial type the same facility exists, but there were Colonial saddles where access to the panels was as difficult as it is in the ordinary hunting saddle of civil life. The Colonial saddle, whether semi-military or not, may be described as, in principle, a roomy hunting saddle possessing D's and other appliances for carrying equipment. The chief failure of Colonial saddles was not so much in shape and type as in quality of material; some of them hurriedly put together for the war possessed wearing qualities little better than brown paper, and this was particularly the case with those manufactured in South Africa. The saddle D's were frequently merely tacked on, instead of being rivetted to the tree or sewn on to stout canvas. Many of the saddles at first used by irregular corps were those specially made for "trading" with natives; they were cheap and worthless. They gave a great deal of trouble from breakage and caused many injuries.

It is obvious that the substance of which a saddle is made should depend upon the living weight to be placed on it, and the dead weight which is secured to it. Colonial saddles are not constructed to carry much dead weight; a blanket, some food and simple means for cooking it, represents all the impedimenta carried. The tree of such a saddle and the substance of the material covering it may be correspondingly light. Its prototype in this country would be a good roomy hunting saddle with some extra D's.

If a saddle, in addition to carrying a man, has to carry all his worldly possessions it must be made stronger in the tree and stouter in its material, and the increase in strength means increase in weight. Consequently it is no use talking about reducing the weight of the Regulation saddle until the question of what constitutes a fair load for a soldier's horse is settled. If it is to be twenty stone, as at present, nothing lighter than the existing material will carry the mixture of dead and living weight.

As a matter of fact, we know that the infliction of such a weight is an outrage on any other than a trained pack horse, and that experience tells us the maximum weight a horse can carry effectively lies between fourteen and fifteen stone. We must never forget that the construction of the horse is adapted for pulling a weight, and not for carrying one; he can effectively haul two-and-a-half times his body

weight, and for short hours and short distances very much more than this, but he cannot effectively carry more than the one-sixth to the one-fifth of his body weight.

If, from the horse's point of view, we were called upon for an expression of opinion as to the class of saddle a soldier should ride on, we would say a strong, roomy, well-stuffed hunting saddle, resting on a blanket, the panels of which can be readily got at. Nothing more should be carried on this saddle than the man's cloak, and food for horse and rider for the day, for which purpose strong attachments, or D's, should be provided. The saddle must be roomy—nothing is so tiring to a man as a short seat, it causes him to be constantly shifting his position, tires his horse, and by twisting the saddle produces injury.

The general verdict on the Regulation saddle was that it was clumsy, heavy and too short in the seat. The causes leading to its sore-back-producing features we have previously glanced at. The Colonial (Staff pattern) saddle was excellent. The ordinary Colonial pattern was satisfactory provided it was made of good material, but the liability to breakage from bad material, defective workmanship and heavy loads was very noticeable. Defective material does not affect the question of type, and the type was good, practically the same as that used by the enemy. The Dutch of South Africa live in the saddle; we may be quite sure that no pattern is adopted by them which is unsuitable for the purpose. During the war every Burgher effected his own saddle repairs. Their profound knowledge of horse management, and the fact that though they never walk a yard they equally never sit for a second on their animals the moment they halt, preserved the backs to a remarkable degree. I have the authority of Sir Arnold Thielier, K.C.M.G., who served as veterinary officer with the Republican Forces, for saying that there were few sore backs among the real Burgher class, but their foreign allies provided them with a large number.

The saddle and equipment carried by the enemy during the war may be seen in Plate ii. It should be compared with that of our men shown in "A Mid-day Halt," Plate i, Fig. 4.

The waste of material in war is always great, sometimes unavoidable, but there are causes of waste capable of control. A "set of saddlery" comprises very much more than a bridle, saddle, stirrups and girths. Wallets, breastplate, numnah, shoe cases, rifle-bucket and innumerable straps go to make up an alarming total.

The system of military accounting demands that a complete set of saddlery shall be issued. Yeomanry and Irregular regiments were invariably anxious to leave the impedimenta behind, as they prevented the men from mounting and dismounting, and only to take the essentials; but an Ordnance issue is "all or nothing," with the result that the unnecessary material was deliberately thrown away, unless the Commanding Officer could secure some place to

store it. What the loss amounted to under this head alone it is impossible to say. Tens of thousands of pounds worth of parts of saddlery and equipment were deliberately thrown away as not being essential, or, as in the case of hay nets, not being required, as there was no hay to carry.

Not many weeks after the Director-General of Ordnance wrote his minute of 15th December, showing that the reserves of Cavalry and Mounted Infantry saddles only amounted to a thousand, a pile of saddles, one of many, might have been seen being burned in the Field to prevent them falling into the hands of the enemy. These belonged to horses which had died or had dropped out, and for the carriage of which no transport existed. When these horses were replaced a complete new saddle was also required. No wonder wars are expensive! The enemy, under similar circumstances, would have buried the saddles, but then he had been differently brought up, and, moreover, he would have been taking care of his own property. In the other case, it belonged to that long-suffering individual the Tax-payer.

The next point to be considered, in general terms only, is defects in fitting, and we here come to a very complex case. The shape and bulk of a horse's back depend upon his condition; with every variation in this there is a corresponding variation in the shape and size of the back, and, strictly speaking, it can never be said in war that a saddle fits; it may fit to-day and not to-morrow. The tendency on service is for the saddle to become large, for the reason that the horse's back is becoming smaller. This is the explanation why the most constant supervision is required; on a campaign there is no finality in saddle fitting. The saddle rests on the muscles and not on the bones: the muscles are growing progressively smaller but the bones do not waste, they seem, in fact, to grow larger as muscle-waste takes place. The liability to injury is increased day by day, as a consequence of the saddle, man and equipment coming nearer to the bony framework. Not only do the muscles become smaller, but this is followed by an alteration in their shape, so that the weight is no longer supported in the same way.

With every alteration in the muscles of the back there must be some addition to the material beneath the saddle if the latter is to maintain its proper position above the spine. In what way is the loss of back-muscle in war to be replaced? This is one of the problems in saddle fitting which the sanguine at one time believed was solved. It can only be effected by the addition of a saddle blanket to the hair panels. But if the account which has been given above is clear, it will be seen that when war broke out the Cavalry had no hair panels to their saddles, they had been taken away, and with their abolition the flood-gates of disastrous back-trouble were opened.

Whether the horse be for military or civil riding the saddle must always be at a definite height

GROUP OF HORSES IN A BOER COMMANDO.

Note the trifling amount of impedimenta carried on the saddle.

The class of animal used by the enemy is also well shown. The weight they carry may be judged from the tall broad-shouldered man holding them, who is typical of his race.

to you  
Annex 1A0

.

above the spinous processes of the dorsal vertebræ, but, whereas for civil purposes the clear space may be small, for military purposes it must be much greater, owing to the heavier weight placed in the saddle, and the daily shrinkage of flesh. The saddle is kept above the vertebræ by the means we have just mentioned, *i.e.*, extra stuffing in the panels. Where there are no panels the extra material can only be given by placing a second blanket beneath the saddle. Two blankets and a numnah now lie across the ridge of the back and fill up the air channel which should naturally exist at this part, they also fill up the front arch. By filling in this space pressure is brought to bear on the spine and withers, so that the very measures employed to replace loss of flesh on the back may be the means of injuring the spine. On the contrary, if no second blanket be used, the loss of muscle will subsequently prove so considerable that the saddle will, as a consequence, actually rest on the spine and withers. A few minutes of this will give the horse a sore back, which may take weeks to cure.

The presence of hair panels largely abolishes the terrible conditions above outlined; for extra stuffing can be placed in a panel in a few minutes,\* or a saddle blanket employed. The channel of the saddle will accommodate one blanket plus numnah, but not two blankets, while the panels, practically, do not interfere with the channel.†

The defects in fitting which occur through saddling up in the dark can only be fully realized by those who understand how essential daylight is to such an operation. Even the most careful man may, when day breaks, find the loose end of a strap between his horse's withers and the saddle, or a buckle resting on the spine. In both of these cases injury will surely result to this remarkably sensitive part.

Defective fitting comprises many faults, not only those mentioned above, but many others into which we cannot here attempt to enter.

Defects in the horse are those associated with make and shape. High, lean, razor-like withers are sure to become injured on service; an animal with indifferent muscular development of back-muscles gives nothing for the saddle to rest on; a narrow back instead of a full wide one carries the load too low on the ribs. A round back is liable to be injured over its greatest convexity; a hollow back is injured at the two points front and rear

\* Under stress the extra stuffing need not be hair or wool; hay, grass, straw, even leaves or paper, may be substituted. In South Africa wool was available almost everywhere. General Rimington says, with a good deal of trouble he could make the Colonial saddle suit almost any horse by adjusting the stuffing and putting in wool or hay ("R.C.", Q. 12,735, *et seq.*). Colonel Thorneycroft who used nothing but panelled saddles, says that restuffing caused no difficulties to the one saddler he had per Company ("R.C. App. 52").

† The use of the saddle blanket beneath the panelled saddle is invaluable when Colonial ponies lose condition in the field, but its efficiency depends entirely on the supervision of the officer. [Thorneycroft *loc. cit.*]

where the saddle rests. Conformation plays, therefore, an important part, more especially among horses bought in a hurry for use in war.

Defects in management are so many that we can only indicate some of the principal. If men are allowed to sit on their horses all day nothing can prevent sore backs. It was a cardinal principle in the Cavalry in years gone by never to be seen off one's horse; it was considered undignified. Prejudice and ignorance die hard, and as the alternative to being on the horse's back is walking alongside him, the human element comes into operation, for who would walk when he could ride? Over and over again during the campaign attention was drawn to the importance of Cavalry dismounting at every opportunity. It serves, of course, two great purposes, it relieves the back from weight and so gives the muscles an opportunity of rest, and it admits of the blood circulating through the skin of the back after being pressed out of it under the influence of a weight of 20 stone. If horses are led in hand when military conditions render it possible, and a practice established of dismounting every hour, if only for a few moments, and, if circumstances admit, loosening the girths, exhaustion is not so likely to occur and backs are saved. One has only to read the evidence before the R.C. of a Cavalry soldier like Rimington to realize what is possible in the hands of a horse-master in the matter of saving wear and tear. (See p. 237).

The other defects in management might be embodied generally under defects in horse-mastership, for everyone ought to realize the prime necessity for hard condition before severe work is attempted,\* the readiness with which "soft" horses gall, and the paramount necessity of watering and feeding whenever possible. The distance between these and back trouble is not great. Even the roller of the blanket used at night may be a fruitful source of trouble if drawn tightly—as men invariably do—to keep the blanket from coming off. The wise Squadron Commander knows how the web shrinks in the rain or heavy dew, and has them eased accordingly. The master's eye must be everywhere, he must have knowledge, judgment and imagination.† The growth of the latter is inhibited by a

\* For this defect in horsemastership during the war the Regimental Officer was not responsible.

† A very good example of defect in this respect is given in the "Imperial Yeomanry Report" of 15th May, 1901, and "Supplement" of 1st January, 1903, "Parliamentary Papers," Cd. 803.

Some 300 pack saddles had been provided for the use of this Force. Complaints were sent home that the saddles were too small, and samples were ordered to be returned for inquiry. On their arrival it was found that the complaints arose from a complete misunderstanding as to the packing of the saddles; straw and horse hair stuffing employed to prevent the trees breaking in transit had not been removed!

The writer remembers a saddle, with a mechanical tree, being issued for experiment many years ago; a report was made on this saddle without the peculiarity in its construction being known. The panels had never been removed, and the mechanical contrivance for self-fitting lay within them unknown to the regiment conducting the trial.

cast-iron peace system, and paralyzing regulations; fortunately these can be thrown to the winds in war, and scope given to originality.

Bad horsemanship as a cause of sore back was very evident during the campaign. How could it be otherwise with men sent into the Field who had never previously ridden?

Rolling and twisting in the saddle are common causes of sore back besides being most exhausting to horses. Much of it is caused by the seat of the saddle being too short. The moment the men sit askew to take the weight off the ischii they should be dismounted. Bad horsemanship runs hand-in-hand with bad saddling; what could a man know of saddling who had never previously put one on a horse's back? We need not labour the point, it is almost unbelievable that such things could have happened.

The weight carried is the crux of the saddle question. If 20 stone has to be carried, the saddle requires to be much stronger than if only 15 stone is being carried. Those five stone make all the difference between whether a roomy hunting saddle can be used, or one suitable to carry a "man-at-arms."

No horse should be asked to carry more than 15 stone in weight all told; the service weight is 20 stone. At present the horse has to carry the rider, his arms, ammunition, accoutrements, picketing gear, food for horse and man, necessities and comforts, the whole placed upon, or strapped upon a contrivance which has to be of immense strength to stand the strain. *It is almost incredible that the animal is inflicted with the equivalent in weight of two men.* There seems no escape from a crushing weight so long as it is considered necessary to send men into the Field with anything more than their arms and ammunition—more than that, with the man's cloak and food, and the horse's corn, ought never to be placed on the back. General Rimington, during the war, got the weight of his Scouts down to 14 or 14½ stone all told. Too much credit cannot be given to this officer for the manner in which, immediately the war began, he grappled with the question of the weight carried. He was a Cavalry soldier, yet it is doubtful whether his influence in this matter was felt, even though Lord Roberts spread his views broadcast by the publication of an order. The fact is that material has to be carried at the expense of the horse for which light transport should be provided. It cannot be that it is considered cheaper to weigh down the Cavalry rather than provide them with transport; it can only be due to the fact that the limitations of horse power are not understood. Our Cavalry can never be effective until the weight is reduced to 14 stone, 15 stone being regarded as a maximum.

Haig, in his evidence before the Royal Commission, Q. 19,449, *et seq.*, regarded 14 stone as the weight to be aimed at. He found with the ordinary regulation saddle, when it was stripped of everything and the man allowed nothing more than what he stood up in, together with cloak, waterproof sheet, soap and towel, arms and ammunition,

one day's food for horse and man, that the weight could not be got below 17 stone 6½ lb. The man, stripped, weighed 10 stone 12 lb., which is too heavy. Reservists were, of course, much heavier than this, a fact which must ever preclude the Cavalry Reserve from being a reliable source of strength.

Rimington, R.C. Q. 12,656, *et seq.*, got his irregular regiment down to 14 to 14½ stone. To secure this, the men rode as they stood, together with cloak, food for horse and man. He cast away wallets, change of clothing, grooming kit, shoe cases, spare shoes, hay net, spare boots, picketing gear, breast plate, hoof picker. The spare material was carried in wagons. (See R.C., Vol. i., p. 531, App. H, and Vol. ii., p. 28).

Thorneycroft's men rode heavier, as they carried wallets weighing, when filled, 9½ lb. In the R.C. Appendix No. 52, p. 351, he gives details of his equipment. The lightest of his men appears to have ridden 16½ stone, but, even then, much lighter than the Cavalry.

General French, in his evidence, R.C., Q. 17,194, *et seq.*, said that the Cavalry soldier should have nothing on him but arms and ammunition. Discomfort would ensue, but this must be risked, even to going without food, for, as he adds, "It is absolutely impossible, if Cavalry are to do their work, that they can be laden as they were in the last campaign."

There is no part of a mounted soldier's equipment which offers greater temptation to the rider to carry weight than the wallets; anything and everything finds its way there, the most tempting souvenir being an unexploded shell. Wise Commanders soon cast wallets to the winds.

We do not intend to pursue this question of weight further. No one with knowledge defends it. If Cavalry are going to ride 14 stone in future vast changes will have to be made in the organization of this arm, including the provision of transport, for that which is at present carried on the horse.

It can be seen, in spite of the rapid survey we have made of the question of sore backs, that the sources of injury are many, and that though a dozen horses may be suffering from sore backs, not two of them may be due to the same cause. We cannot here attempt to specify the number of distinct injuries which occur, but each has its own definite position on the back, and each tells its own story. The position, then, of an injury is not a matter of accident, and this being so, the position of the injury, to the trained eye, reveals the cause of the trouble. Once this lesson is learned the next step is arrived at. If the cause is known it can be removed, and if it be removed further injury ceases. Thus the story is built up step by step, with an exactitude which depends upon the powers of observation of the squadron authorities. Simple as this may seem, it is the basis of effective legislation, and effective prevention and cure. In days gone by a sore back was a sore back, no matter where it

occurred; it might be under the seat of the rider, or in front of his thigh, or on the top of the spine behind, or on the play of the shoulder. We now know differently, and that each position of an injury on the back is distinctive of some special cause. We have, in fact, an accuracy given to back inspection and saddle-fitting which, in skilled hands, reduces it to almost mathematical precision.

This, however, can only be attained in one way, and that is by daily inspection. The officer on service who neglects to inspect the back of every horse daily fails in one of his first duties to the State. The example he sets in this matter is the one which is followed by all under him. There is no more uncommon thing in war than fighting; the days in a campaign are made up of a lot of marching and very little fighting. Peace manoeuvres, in this respect, are most misleading. The back inspection, spoken of above as a daily routine, can be carried out if time and opportunity be taken, and it is seldom that these are absent for even a day. The value of such an inspection is of the same utility as the "stitch in time"; the rub of to-day becomes the sore of to-morrow.

It is rather a matter for surprise that so few officers are skilled in the subject of saddle-fitting and the prevention of injury. They are all glad for their horses to escape without sore backs, but few show any real natural aptitude for this study. The tendency to work horses with sore backs rather than report them sick (see p. 59) is only justifiable when the squadron officer is capable of effecting such alteration as will enable the horse to work without further injury occurring. It is probably the theoretical simplicity of saddle-fitting which causes its practice to fall far below the requisite standard.

The relative proportion of the various injuries on the back which occurred during the war cannot be stated with even approximate accuracy, as records are not available, but it is safe to say that the withers and spine were three, perhaps four, times more frequently affected than any other region. This fact alone tells its own tale of defective equipment and want of supervision. A good object lesson is conveyed in Plate i., Fig. 4, which shows the halt of a column at mid-day. The amount of impedimenta carried on the saddle may there be seen, even when much has been lost through wear and tear in the campaign. The top weight oscillates, while the want of adjustment of balance causes the saddle to heel over and press against the withers. So important is the adjustment of weight that it is better to carry weight for the purpose of adjustment, than ride with one side of the saddle heavier than the other. An examination of Fig. 4 shows that the officer in command did not understand the importance of balance, or he never would have allowed a rifle to remain in the bucket, causing the saddle to heel over. Adjustment of weight is always a difficulty. A feed of corn carried in a nosebag may help or disturb matters; under any

circumstances it is a fluctuating quantity, for the bag is getting lighter as the day advances. Apart from the balance of weight the arch of the saddle may touch the withers. It is impossible for any mounted man to fail to detect this with his finger; a saddle resting on the withers is the cause not only of horrible suffering but prolonged, and frequently incurable, injury. A child could ascertain its existence when shown how, so that injured withers, besides being the most common, are also the least excusable variety of back injury. Many injuries were caused to both the withers and spine by the colonial saddles, for these were rarely wide enough in the front arch to prevent pinching, or curved up enough behind to clear the spine. The Australian stock-saddle, with its crupper staple, was a prolific source of trouble in this respect. After the withers and spine, the next place most commonly injured lay under the point where the rear arch is attached to the side-bar.

Whatever is carried on the saddle must not dangle about, but be securely fastened and all movement prevented. Nothing tires a horse so quickly as oscillating weight. If some satisfactory means for carrying the rifle could be found, other than attaching it to the saddle, it would be of material service to the horse. Dead weight attached to the saddle is more harmful than when the same weight is carried on the man's body. It is also easier for the horse to carry spare ammunition in a bandolier placed around the neck than to carry it on the saddle, especially in the wallets, where it aids indirectly in producing wither pressure.

It would be wrong to convey the impression that all sore backs are capable of prevention on service. When animals get below par the liability to injury is increased, and when, in addition to this, there is great wasting of the muscles of the back, the avoidance of injury due to the weight imposed is extremely difficult, for it is on these muscles that the weight is carried.

The Regulation head collar and bridle are generally represented as being too heavy. We agree as regards the bridle, but a head collar must be stout, for it experiences very great strain when the horse is tied up.\* The bit is unduly heavy and of a wrong pattern. The bit and snaffle (bridoon) should be combined, and not in two distinct parts as at present, necessitating four reins. A single pair of reins should suffice, as in the Mounted Infantry bridle. Our present Cavalry bit is an instrument of torture in heavy hands, and "hands" are given to few men. On a long, hot and exhausting march it is a good practice to remove everything from the mouth, and ride the horse with the head rope placed over the nose. Parching of the mouth then occurs less readily.

\* It might, however, be made of canvas, like a ship's head collar.

*TRANSPORT BY SEA.*

The old system of transporting horses by sea was to place them in a narrow and short stall, and put a sling under them. No attempt had been made officially to improve on this system until 1899, though the sea transport of horses was known to be attended by mortality, which was frequently high. In 1887 important improvements on the existing system were suggested. It is gratifying that the new ideas, if not originating with the Veterinary Service, were first put forward by it, and to Colonel Duck must be given the credit of drawing attention to a better system of carriage at sea.\* He had gained his first experience in the Abyssinian War of 1869, when he observed, in the transport of mules, that the stalls were too short and the breast bar too high. The closely fitting "crate" into which an animal was packed, in what we shall term the Admiralty fitting, did not take into account, nor allow of, an animal altering the position of its body in order to maintain the vertical attitude during the rolling of the vessel. It is obvious that to effect this he has to "hang back" when the roll is from him, and lean forward when the reverse movement occurs. In a short stall, such a to and fro movement is impossible, and the foot hold is consequently lost. To compensate for this the sling was introduced to prevent the animal from falling, and in bad weather, when this was tightened, he behaved in it as a pendulum, and bumped to and fro.

When the introduction of steam facilitated the transport of horses by sea from one continent to another, the margin of profit could only be satisfactorily increased by cutting down expenses. The first regular, and at the same time most difficult, passage established for horse-ships under steam was between Australia and India, and the shippers in these used, for economy, a pen holding four or five animals, instead of a separate stall for each, and, to further reduce expense, did away with slings. They depended upon a good foothold to keep the animals from falling. They experienced a good deal of loss at times through fittings giving way in bad weather, but proved the important fact that slings were unnecessary to keep a horse on his feet. As a matter of fact, if tightly drawn up to the body, they actually carry him off his legs, and become a positive evil. It is not essential to this history to know all the sources through which this information was obtained. We assume that the Australian trade with India was the first on a large scale, but the Arabs, probably for centuries, have been shipping horses to India from the Persian Gulf, and though, of course, they chose their season for the passage, the arrangements for the animals were of the most primitive character. When the Trans-Atlantic trade opened up, and the shipment of horses from America ran into between twenty and

thirty thousand animals a year, no slings were employed nor were separate stalls used. Boats were specially built, the pens having a maximum size of 15 feet x 9 feet; horses and cattle travelled in the same type of vessel. There were individual heavy losses but the average was remarkably small,  $2\frac{1}{2}\%$  and under for horses. The voyage, of course, was short, and the temperature may be taken as uniform, compared with a ship going from north to south.

Just before the war a Committee of War Office and Admiralty Officials was appointed to consider the question of the sea-transport of an Army Corps. Among other matters, that of the transport of horses had to be dealt with, and for this purpose Colonel Duck was a member of the Committee. The principles he laid down on this question in 1887 were those which he placed before the Committee, and he urged that a stall of greater length should be furnished. He pointed out that the short stall of six feet, in bad weather, did not give the horse sufficient room to resist the rolling of the ship, and that it was impossible for the animal to get his hind quarters far enough back when the decks were at a steep angle. In consequence, he was either shot forward against the breast bar or rubbed his quarters raw. By lengthening the stall the animal was given room to maintain his vertical position during rolling, and no slings were then necessary to keep him on his feet; in fact, the latter were, as explained above, even harmful.

Having given the horse room to move to and fro for the purpose of vertical adjustment, it only then remained, as Colonel Duck pointed out, to give him a reliable foothold in order that he might maintain his position. On this point he laid the greatest emphasis. What could men do in bad weather if everything they laid hold of to save themselves gave way under stress? The position is identical with that of the horse, which has to try and save itself through its legs, and will succeed if only he obtains a firm foothold against which he can press.

At this time—July, 1899—there were in store old pattern short stall fittings for 10,000 animals. The Committee urged that more modern measurements should be adopted, and money provided to furnish 6000 new fittings. It was not, however, until September, a few days before war was declared, that the Treasury approved of £25,000 being spent on fittings for horse transport.† Of course, these had not been put in hand when war occurred, the result being that only fittings of the roughest kind could be provided.

Another question dealt with by the Committee was the utilization of cattle boats as horse transports, a point urged by Colonel Duck, from personal experience, and supported, for the same reason, by General Truman, the head of the Remount Service. This turned out an equally satisfactory measure, and these vessels were subsequently largely employed.

\* "Veterinary Hygiene," F. Smith, 1887, p. 297.

† R.C., Q. 2356, 9534.

This class of ship was specially built for the trade, and was furnished with bilge keels to keep them steady, water ballast, and ballast tanks, the latter not found in other types of ship (R.C. Q. 9807.) The water ballast enabled a large supply of fresh water to be carried, which was replaced as ballast by salt water let in. The vessels also were well drained, and naturally adapted themselves to the erection of stall fittings, in place of the pens usually employed in the trade. The standings were cemented. The existing number of ships of this type was obviously limited, and, as matters turned out, many were employed which were not designed for animal transport.

It is noteworthy that in the subsequent official inquiries both the Inspector General of Remounts\* and the Admiralty† laid claim to originating the new fittings. Colonel Duck's name does not appear.

This general statement enables the position of affairs at the outbreak of hostilities to be understood. The old system of carrying horses in short stalls was in theory discarded, and trade methods adopted. In one respect we carried this too far, and that was in the neglect of sanitary precautions, a matter not so obvious in a short trans-Atlantic passage as in a 30 days' journey, part of which was through a tropical zone.

When war broke out on 12th October we possessed no new fittings, but the Admiralty showed their usual promptitude in dealing with a situation where common sense and energetic action are required. Plans of the new fittings were soon got out, a small army of carpenters employed, and in a few days fittings corresponding to the recommendations of the Committee were erected on the transports. They were rough, of green and undressed timber, and long French nails were employed where screws only should have been used. They possessed one great defect, and that was the weakness of the slot into which the parting boards between each stall were placed. The slot was not only too shallow, but was formed by two pieces of wood being nailed on to the uprights, or stanchions, of the stall. When this weakness was pointed out to Naval Transport Authorities it was not considered by them to be important, and the Veterinary objections were overruled. In a few days they purchased, at public expense, a lesson to which reference will be made later. In spite of the haste the troops were on board before the fittings were completed, and the ships, in some cases, left the dock with the carpenters still at work. ‡

\* C. of E. Rem: Q. 1718, 4410, 4530.

† R.C., Q. 9793, 9804.

‡ It may be noted that it takes 12 days to fit up a troop transport to carry Cavalry. The tonnage allowed to a horse on a transport, that is, a ship carrying troops, is 11½. In Remount ships 6½ tons per horse, and 3 tons per mule were allowed; the mule tonnage is only one-fourth that of a horse, as they are carried in pens instead of stalls. In consequence, a ship which carries 700 horses would carry 1000 mules. (Q. 4517.)

The scale of measurements laid down for stalls and gangways was excellent in theory, but frequently fell short in practice, especially towards the ends of the vessel. Here it was difficult to walk between the animals' heads excepting by going sideways. There must be ample passage room, not only for the purpose of ventilation, but for exercise. It is wholly wrong that horses should be almost head to head, each breathing the vitiated air of his opposite neighbour. Especially was this the case in those ships carrying Remounts under freight charter, where the owners' chief object appeared to be to stow away as many animals as possible irrespective of sanitary requirements.\*

The lengthening of the stalls from six to eight feet carried the standing up to the side of the vessel. There was consequently no alley-way behind the horses for the purpose of clearing out the dung. This had been anticipated, and the objection was met by the Authorities saying that in the trade the standings were not cleaned out during the voyage, and that the troop horses were to travel under similar conditions. This showed a want of knowledge of the amount of excreta a horse produces in a voyage of thirty days; behind mares it was a foul pool of pulsatious faeces fetlock deep; behind geldings it was a mound which raised their hind quarters considerably above their fore hand, and threw considerable strain on already tired fore legs. In the C. of E. Rem: a strong effort was made to ascertain who was responsible for giving this order, but nothing definite resulted. As a matter of fact, on transports carrying troops the putrid mass had to be removed, as its overpowering stench cannot be described. On Remount ships the labour for cleaning out the stalls did not exist, and for 30 days the hind feet were either buried in a quagmire, or the horse standing down hill.† Cleanliness is the keynote to efficiency on board ship. There are sufficient other detrimental causes affecting horses without adding to them and, moreover, ruining the hind feet.

It is not our intention to enter into details of construction of the stalls employed, but only to indicate general principles, and the weak points in those erected for transport purposes during the war. To one of these allusion has already been made, i.e.,

\* The Admiralty approved of a Remount boat, the "Manchester City," which subsequently turned out a "Black Hole." They accepted the owners' statement that she would carry 2500 mules without apparently verifying the calculations. She carried 2000, about 500 too many, and experienced shocking losses, an account of which is given later. See C. of E. R., Q. 4176, 4397, 4413, 4415, 4442, 4445, 6155.

† This, and another equally unsatisfactory ship, the "Anselma de Larrinaga," were both engaged, not only under freight charter, but the owners were permitted to carry the animals as they would do their own, an objectionable clause which encouraged overcrowding, and robbed the conducting officers of the right of veto.

‡ We shall see presently the trouble in which this involved two Veterinary Surgeons. Yet the Authorities, when they reported these cases, must have known that all Remount ships were in a similar condition.

the side bars dividing the horses, which were not only too weak in substance, but too shallow. The slot, it will be remembered, consisted of two pieces of wood placed parallel to each other and *nailed* to the upright. These were frequently kicked away, and the boards fell out. The slot ought to have been cut into the uprights, and the boards would then have been secure. The breast bar on Remount ships was generally one long piece common to four or five stalls, so that in order to take a horse out of his stall, the bar in front of four or five others had to be removed. The breast bar for each stall should be distinct, as on troop transports. The bar also must be a different height for horses and mules. If too high with small animals it injures the front of the neck. There must always be three stanchions to two horses, and not two, as in some Remount fittings. The flooring must be of wood, with cross battens placed in the right position for catching the feet. These battens must be thoroughly well secured, as there is a great strain on them. The importance of a sound flooring cannot be too strongly insisted upon. In bad weather everything depends upon the horse maintaining its foothold, and this can only be ensured by good and properly placed battens. If these are not in the right position, there is nothing for the feet to press against. It is convenient to have the flooring in two pieces, for facility of lifting, as the deck beneath requires flushing. The haunch piece must be hollowed to receive the shape of the animal, or be, at least, rounded. Some horses rest against it when tired, and, in a short stall, this is a normal condition. If the timber is not round it causes injury.

Mangers should be of galvanized iron, and removable from the breast bar. They must be furnished with two bars, which prevent the horse from throwing his food out. They should be washed out under the hose every day. Spare mangers should be carried. The canvas head collars of the ship should be in three sizes. A large head-collar on a small horse causes the nose band to compress the nostrils: a small collar on a big head cuts the jaws, and leaves no room for movement during mastication.

Feeding on long hay is always a wasteful process: on board ship there is no word which adequately expresses the loss so occasioned. If the hay is placed in the mangers it is simply thrown out by the horse, and trampled under foot. Long hay should always be placed in hay nets, small quantities at a time. It necessitates slow feeding and keeps the animals quiet. Watering is a feature which requires the supervision of the officer; every pail of water has to be carried and lifted up to the horse, and men will not do this unless supervised. The importance of ample water cannot be exaggerated, especially in passing through the tropics, and for those horses placed near the engine room.

During the War the feeding of animals on board ship was defective, especially at the beginning of the campaign. Commanding Officers were cautious

to nervousness, so afraid were they of overfeeding with grain. So marked was this in some cases, that on the advice of the P.V.O., the General at Cape Town cabled to the War Office, in February, 1900, that it was better some horses should be lost from overfeeding, than that animals should arrive full of soft food, and quite unfit to work.\* Later, as experience was gained, the feeding became more liberal. Sometimes the forage was to blame. If a ship goes to sea with defective food on board there is no changing it. Such cases were known, and resulted in the condign punishment of those officers who passed the forage. Insufficient food may occur from a breakdown or other delay, and this was anticipated by a week's extra rations being placed on the ship over and above the amount required for the voyage. Cases occurred where forage was short shipped, and horses were landed in lamentable condition. One of these we shall be compelled to look at in detail.

In a voyage lasting a month, it is certainly sound practice not to overdo the grain ration during the first week; but to reduce it to one pound a day, as we have seen done, is an absurdity. During the last fortnight of the voyage the animals may be more liberally fed with grain. There is a good deal of waste in feeding, especially with hay. Only small quantities at a time should be placed in the hay nets, say two pounds. It takes a long time to pull this through the mesh, but it avoids the sinful waste which generally occurs, and keeps the horses occupied. Carrots or roots are excellent, but they keep badly at sea.

The conveyance of mules is in principle the same as that for horses, with the exception that they are not usually placed in separate stalls, but in pens holding four or five animals. The mule is a better sailor than the horse, more placid and philosophical. His worst feature is that he eats his fittings, and reduces them to matchwood. All parts exposed to his teeth should be sheathed with iron. Similarly, head ropes are of no use, they are eaten in a day or two. Nothing but chains should be employed.

Something must be said of the Transport arrangements if we are to understand the conditions under which the animals were carried. The Admiralty conveyed all troops together with their horses. Such ships were engaged on time charter, the Transport Department providing the coal and paying all dues. These ships were specially fitted for men and horses in home ports, according to principles previously arranged. The Admiralty also conveyed all remount horses (not accompanied by troops) from the United Kingdom, and mules from everywhere. Ships for remount horses and mules were differently engaged; the animals were carried on freight charter at so much a head, and the capitation rate had to cover cost of fittings, forage, attendants for the care of the animals, water, utensils, and every other charge. Beside the Capi-

\* Cd. 963, Cable 32.

tation rate there was a bonus for each animal landed alive.

The two different systems here indicated may be described as hired transports, and freight ships, and this distinction must be borne in mind if we are to understand the differences in management, and difficulties which subsequently arose.

The Admiralty, however, did not make arrangements for the transport of all the remounts purchased. Owing to their hands being full, the Inspector General of Remounts made arrangements of his own with a Shipping Company, for conveying horses on freight charters, and for seventeen months this system continued, until finally the Admiralty took it over.

The capitulation rate was at first calculated on the number of animals embarked, but was subsequently divided into two parts: one being paid for each animal taken on board, and the other for each animal landed. In this way, the interest of the owners in the safe conveyance of the animals was assured.

All animals conveyed in freight ships suffered under a great disadvantage as compared with those travelling with troops in transports. A military conducting Officer and a Veterinary Surgeon were to accompany each freight ship, though, owing to the difficulty of obtaining the services of these two classes, some of the early ships were not so provided.

Conducting Officers possessing the needful qualifications were, no doubt, difficult, if not impossible, to obtain in sufficient numbers. Of 195 so engaged 109 were Lieutenants or Second Lieutenants, and, therefore, of extremely limited experience; further, 34 of this number belonged to the infantry.

Of the total number of Officers of all ranks employed on ships, 70 belonged to the infantry. It is difficult to see, so far as the animals were concerned, what purpose Officers of this branch served. The above figures show what a large proportion of conducting Officers were entirely ignorant of horses, let alone of their care and management at sea.

The Civil Transport Veterinary Service was quite distinct from that created for employment in the Field. Many of the veterinarians were foreigners, and it is now known that some of these possessed no qualification. No matter how experienced a man may be on land, it is certain he has a good deal to learn when he first goes to sea with horses, so it was desirable, as far as possible, to retain the services of those practitioners who had already obtained experience. The evidence of witnesses before the Royal Commission and Court of Enquiry Remounts, was generally to the effect that the Veterinary Transport Service conducted by British practitioners was successfully carried out; there were exceptions, and, no doubt, there were men who, from an absence of personality, failed to make themselves felt.

The care and constant supervision which horses everywhere require is greatly increased on board ship. But for this purpose it is sufficient on troop

transports that one man should look after four or five horses; all men over and above this proportion should be cleared out of the horse decks in order to increase the extremely small air space. On troop transports the difficulty is not to find labour, but to employ it skilfully in the confined space. On freight, *i.e.*, Remount vessels, there were no soldiers; civilians were engaged for the voyage, and the condition of the horses at the end of the journey, other things being equal, largely depended upon the manner in which these men performed their duties.

The proportion of attendants to animals on this class of vessel was fixed at one man to 15 horses or 20 mules; had they been trained men at the work it might have sufficed to water and feed the animals, but not for cleaning out the stalls. They were not, however, skilled men; many knew nothing of horses, nor had experience of the sea; they were drawn from all classes and conditions, and were difficult to keep under discipline.\* Some of the witnesses expressed themselves on this point in more forcible language than the Court, for even mutiny was not unknown.† It must be remembered that in the tropics it is not possible for a man to remain long in the lower decks of a horse ship, especially amid such insanitary surroundings as we have described, without feeling faint or being actually sick, and we are strongly of opinion that the labour provided for the care of the horses on freight ships was insufficient. It ought to have been not less than one man to 10 horses. The Report of the Court of E. Rem.: points out in para. 118, that the master of the vessel did not always concern himself with the way in which the men carried out their duties, and that men were frequently short shipped. Under these circumstances it is not remarkable that horses were landed in bad condition. Later, during the war, there was an improvement in this respect, as the men were prohibited from landing, so that they were no longer being carried in order to enlist in the first irregular corps requiring recruits, or, as was reported, joining the ranks of the enemy.

It seems to us essential that the great difficulties the conducting Officers and Transport Veterinary Surgeons had to contend against in the care of horses on board ship should be clearly realised this is especially necessary in order to understand the cases yet to be narrated.

One witness gave evidence that the labour party (in this case soldiers) was removed from the ship before the horses were landed, and that he and the first engineer of the vessel had to water and feed them!‡

The relationship between the Sea Transport Veterinary Service and the Military Conducting Officers cannot be described as cordial. Their duties overlapped, a fruitful cause of difficulties;

\* Report of C. of E. Rem., para. 119.

† See C. of E. Rem., Q. 5514.

‡ C. of E. Rem., Q. 3991.

there was also a natural ignorance of military system on the part of the veterinary element, and there was the determination of the conducting officer to retain some semblance of the authority with which he was undoubtedly invested. We cannot think that the cause of difficulties and misunderstandings was always on the veterinary side, and some evidence will be quoted in support of this view. Both were in an extremely difficult position, demanding great tact, for each was under the Commander of the vessel, in whose hands the labour party was placed. When difficulties arose orders to the men had to be transmitted through the Captain of the ship, so that the conducting officer frequently found himself in a doubtful and humiliating position of responsibility. \*

The chief cause of friction between the conducting and Veterinary Service arose from interference with purely professional duties. Some conducting officers expected the Veterinary Surgeon to carry out their treatment. One insisted that all temperatures should be taken at the mouth, with the result that the thermometers were soon destroyed. Another suspended the Veterinary Surgeon from duty without good reason. One insisted, against veterinary advice, in shooting, as glandered, every horse with a nasal discharge. This case came before the Court of Enquiry Remounts, who, in referring to the destructions, say, "In so doing he acted upon his own responsibility, without the advice of the Veterinary Surgeon on board." † The full facts of this case were before the Court, and it was known the officer acted *against the advice* of the Transport Veterinary Surgeon, and in spite of his remonstrations, we shall, therefore, give an outline of the case.

The s.s. "Cervona" left New Orleans on 8th Feb., 1901, with 849 horses on board, an Artillery Captain as conducting officer, and a British Veterinary Surgeon. There were many cases of catarrh—a common complaint on board ship—and the Artillery Officer got it into his head that the animals were glandered, in spite of veterinary representations to the contrary. He then stated his intention of shooting them, and was advised that there was no necessity, as the animals were free from contagious disease. He shot no less than 251, representing £17,500, and, but for bad weather, would have destroyed many more, but could not get the carcasses overboard. Including deaths from other causes, he arrived in Table Bay with 571 animals, all of which he regarded as glandered.

It is, perhaps, as well that the statement of the General Officer of Cape Town on the matter should be given; it appears in the Royal Commission, Q. 13,783;—

"One Artillery Officer, on arriving, said that the whole of his horses had been suffering from glanders, that he had already thrown 50 overboard, and regretted that he had not had time to throw more over. On a Veterinary examination it turned out that there had not been a single case of

glanders on board; one or two horses had suffered from something or other, and he threw them over the side wholesale, and the horses adjoining, and the horses two or three off."

It is interesting to note that this astonishing evidence did not provoke a single question from the members of the Royal Commission. The matter, as we have seen, was even worse than was represented. In the C. of E. Rem: General Truman gave evidence, Q. 1903, *et seq.*, that 251 horses were unnecessarily destroyed, and that the Military Officer overrode the decision of the Veterinary Surgeon, and acted entirely on his own responsibility.

The C. of E. Rem: deal with the matter in nine lines, contained in paras. 125 and 182. Here we are told that "he acted on his own responsibility, *without*\* the advice of the Veterinary Surgeon on board." The Court had it in evidence that he acted against the advice of the professional man.

We may complete the story by adding that the animals were examined at Cape Town, and again, by a Veterinary Board on reaching their destination, at Port Elizabeth, and the opinion given was that no case of the disease existed on the ship, and probably never had. This important fact is not mentioned by the Court of Enquiry.

There were two cases seriously involving the credit of the Transport Veterinary Service, to which great publicity has been given, both by published cables and especially by the Court of Enquiry Remounts. We propose, in the interests of the profession, to examine the facts, as they impute charges of grave neglect. The ships implicated were the "Knight Bachelor" and "Monterey," from North America. Their respective Veterinary Surgeons were foreigners, a fact which is not stated in any of the reports.

The horses on these ships were, it is said, in charge of the Veterinary Surgeon, there being no conducting officer. If this were so the position was one of increased responsibility and trust. †

The "Knight Bachelor" arrived at Port Elizabeth from New Orleans on 27th July, 1900, after being 41 days at sea. One thousand horses had been shipped, of which 44 had died (4.4%). The Military Landing Officer at Port Elizabeth reported ‡ that he boarded the vessel on arrival, and found "the whole place inches deep in decomposing stagnating filth." The horses were "literally packed like

\* The italics are ours.

† The Inspector General of Remounts stated, in Q. 6916, that Veterinary Surgeons were not in charge as conducting officers, but only to perform professional duties. He adhered to this, though the case of the "Knight Bachelor" was specifically referred to.

The Court of Enquiry, in their Report, do not settle the point. In para. 176, they say, in the absence of a conducting officer, "the entire responsibility for the safety and well-being of the cargo falls upon the master." Yet, in para. 182, they say, "written instructions should have been given to the civilian Veterinary Surgeons, who, in certain cases, were in sole charge of horses on board ship."

It is difficult to reconcile these three statements. Matters of the deepest importance to us as a body depend upon whether the Transport Veterinary Surgeon could or could not be placed in charge as conducting officer.

‡ C. of E. Rem: Q. 6044.

\* See C. of E. Rem., Q. 3989, 4074, 4076.

† Report, para. 125.

herrings, and even the ship's coal bunkers had been utilised to place them in." The fittings were inferior and flimsy, splintered and wrecked beyond conception. There were only 37 cattlemen to look after the horses, or 27 horses per man. "Consequently no cleaning had been attempted. The accumulated filth of 41 days at sea is better imagined than described. The ventilation of the lower deck was defective, and the steam fans did not appear to have been at work systematically. Many of the water tanks contained putrid water, the mangers were small and unsuitable." . . . "I attribute the semi-starvation the animals undoubtedly suffered from, to the fact that the horses tossing about the hay, as is their wont, led to the hay falling out of the troughs on to the decks . . . . The forage supply placed on board was totally inadequate to the number of horses shipped and the length of the passage, or it had been shamefully wasted. They appear to have run out of hay nine days before reaching Cape Town, where more had to be taken on board to allow of the ship proceeding to this port. The animals, according to the cattlemen's reports, had been fed on bran for ten days prior to the ship's entering port."

"The civilian Veterinary Surgeon put on board to look after the animals . . . . was totally incompetent, and could not have exerted himself in the least. The Cattlemen report that he was seldom seen between decks."

The statement of the filthy condition of the vessel, and the semi-starved state of the horses is supported by a letter from the Divisional Transport Officer, Royal Navy, contained in Q. 6046.

The Veterinary Report by the S.V.O. Remounts, Port Elizabeth, is given in Q. 1861, and is as follows:—

"Nothing could convince me to the contrary that there was not culpable neglect in the feeding of these horses, and the majority of the emaciated showed no symptoms of disease, either past or present, and yet were living skeletons. This in itself distinctly points to starvation pure and simple."

The Court of Enquiry received none of the above evidence on oath, nor were any of the witnesses examined. The statements are accepted as fully established, and in their Report presented to Parliament, para. 117, they give an outline of the case, and conclude by saying, "There was no conducting officer on board, and the horses were in charge of a civilian Veterinary Surgeon, who had been engaged for the voyage at New Orleans, . . . The horses were half starved, and so grossly neglected that it was considered that the majority would be useless."

The entire onus for the condition of these horses is placed by the Court on the civil Veterinary Surgeon in charge. Yet five features stand out very clearly; (1) The Inspector General of Remounts told the Court that the Veterinary Surgeon was not in charge (see foot note, p. 256); (2) The Veterinary Surgeon was not responsible for the overcrowded state of the vessel; (3) Nor for the short shipment of forage; (4) Nor for the bad type of manger; (5) Nor for the short shipment of cattlemen. For these deficiencies the Remount Authority at the port of embarkation must be looked to, and, as a matter of fact, this was the view taken by the Secretary of State, who, in consequence, directed him to be recalled from America (see C. of E. Rem. Q. 6059). Nowhere in the Report made on this vessel by the Court of Enquiry is the Remount share in the disaster referred to, or the Secretary of State's action thereon mentioned, though the facts were

before the Court. The omission is perfectly unaccountable.

But the case is even still more unfavourable to the Remount Authorities, for it was by the order of the agents of the Remount Department that the stalls were not cleaned out. Every effort made by the Court failed to ascertain who actually was responsible for this as a general order for all ships, transport and freight.\* It was known to be the method followed in the trade (see p. 253), and in the Cavalry (see p. 234), and was approved by the Inspector General of Remounts (Q. 1676, 6878), himself a Cavalry Officer.

Under instructions received at New Orleans the veterinary surgeon on the "Knight Bachelor" did not have the stalls cleaned out (Q. 6052), nor would the labour on board have secured this even had he gone contrary to his orders. We have it also in the evidence of the Remount officer at New Orleans (Q. 1247), that the "Knight Bachelor" was a ship that he always had a difficulty in getting properly cleaned [in port], and to effect this he had three times more trouble with this vessel than any other. For this unsatisfactory state of affairs he blamed the captain and crew (Q. 1243).

In the face of this evidence, all of which was before the Court, is it possible to hold the civil veterinary surgeon responsible for the filthy condition of the "Knight Bachelor" on her arrival at Port Elizabeth? Not a word of the above appears in the Report of the Court of Enquiry to assist in explaining the disgraceful condition of this vessel. The report of the military landing officer is the text of their indictment.

One might have thought that the "Knight Bachelor" was the first vessel to arrive in Africa with stalls on the "Continental system" (see p. 234). But more than 260 vessels had entered one or other of the four South African ports between the outbreak of war and the arrival of the "Knight Bachelor," and all were in principle, if not in practice, arranged for on this system. It was only on troop transports that the abomination could no longer be tolerated, and a superabundance of labour was available for clearing away the accumulated filth from beneath the horses.

We, therefore, submit that the veterinary surgeon of the "Knight Bachelor" was not morally responsible for her condition, that her overcrowded state and shortage of labour rendered it practically impossible to clean her, while the condition of horses was due to insufficient forage having been placed on board. We cannot help but feel that the Court should have arrived at the same conclusion.

The Court charges this Veterinary Surgeon with incompetence. He may have been incompetent, but there is no evidence to that effect, excepting

\* See "C. of E. Rem. Evid.," Q. 1673 to 1676, 1678.  
Q. 4975 to 4978.

Q. 6877 to 6924.

See also Report, paras. 181, 182.

the *ipse dixit* of a layman, an Army Lieutenant, whose report we have quoted.

There was, however, in this case a feature most disgraceful if true. The Military Landing Officer, in continuation of his report, in Q. 6044, says:—

"The same Veterinary Surgeon, when ordered to proceed ashore to report his arrival to the O.C. No. 2 Remount Depot, did not do so, and had not done so up to the time he sailed in the ship without orders. When he did come ashore he became hopelessly intoxicated."

The C. of E., it will be remembered, had none of this Officer's evidence on oath, and no man can be convicted of drunkenness unless on corroborative evidence, of which there appears to have been none. The official statement is that he did not report himself, and it would seem, therefore, that the charge was made on hearsay, which no court of jurisdiction would accept. Nevertheless, the C. of E. Rem. state in their report, that he "*came on shore*" in a state of intoxication! No such statement occurs in the official report of the Military Landing Officer; he is there charged with becoming drunk while ashore, and, without in any degree condoning the reported state of this man, there is as great a difference in coming ashore drunk from his ship, as there is in an officer going drunk to mess—which is a court martial offence—and returning drunk after mess.

Nothing appears to have been omitted which could tell against this Transport Veterinary Surgeon. In the report of the Military Landing Officer the cattlemen are quoted as his authority for saying that the Veterinary Surgeon was seldom seen between decks during the voyage. It may have been so, but the statement of men from whom he had, under evident difficulties (see Q. 1243), to extract work, should not be permitted to carry weight, especially, as we have the authority of the Assistant Inspector of Remounts, S.A., for saying, they were "the riff-raff of the New Orleans and Liverpool slums."†

Even the small mortality on the vessel is not permitted to tell in the Veterinary Surgeon's favour, for the Military Landing Officer actually stated that he ascribed the low rate of mortality "entirely to the hardness of the poor animals, in spite of the criminal neglect they have been systematically subjected to!" It is difficult to conceive a statement of greater prejudice. We cannot help blaming the Court of Enquiry for not stating the whole facts of the case, and for too readily adopting the report of the Military Landing Officer. We submit that, bad as were the facts connected with the "Knight Bachelor," the entire blame should not have been placed by the Court on the Transport Veterinary Surgeon, and this was the view of the Secretary of State for War. We blame him, but for a different reason to that given by the Court. He should have refused to take Veterinary charge of a vessel so

overcrowded and with insufficient labour on board. These were facts patent even to a layman. The flimsy state of the fittings and the small mangers were also obvious, and ought to have been objected to, if he were actually in charge of the horses as conducting officer. He could know nothing of the shortage of forage. He was told not to clean out the stalls. The unsuitability of this dark and slow ship cannot be placed to his credit, as it was engaged by the agents of the Inspector General of Remounts. We blame him if, as is stated, the drinking water in the tubs was putrid, assuming that the supply in the tanks of the vessel was sound and sweet, for these he could himself have emptied on the deck. As to his reported condition ashore, we have seen reason for believing that all the elements for a mistake exist, as he never reported himself.

The second case is that of the "Monterey," which left New Orleans on 7th August, 1900, with 1168 horses on board, in charge, it is said,\* of a Civil Veterinary Surgeon, a foreigner. She arrived at Cape Town on 10th Sept., and the vessel and horses were inspected by the Staff Officer for Remounts, who was "satisfied as to the condition of the horses and the ship, excepting as regards the mucking out."† The Captain of the vessel, stated to the owners (Q. 5999, 6012, C. of E. Rem.), that at this inspection he was complimented on the appearance of the horses. The ship did not disembark her horses at Cape Town, but proceeded to Durban. On her voyage to this port, which occupied five days, she met with heavy weather. On her arrival at Durban, instead of the horses being at once disembarked, the ship was anchored at sea, outside the harbour, and kept there for two days, where she rolled incessantly. In the finest weather a ship rolls heavily at this point, and at the time we are speaking of a gale was blowing. At the end of two days she was brought into port, and the vessel and horses inspected by the Assistant Inspector of Remounts, Natal.

His evidence, given before the C. of E. Rem., is contained in Q. 2832. He stated that the vessel was in a "deplorable condition; the horses frightfully overcrowded, up to their hocks in muck, and in miserable condition." The number of deaths during the voyage was 25, or 2.14%. "Only 500 horses were fit for issue on landing, the remainder being too debilitated to warrant any hope of their being fit to send to the front within a month."‡ The witness attributed the poor condition of the horses to "the faulty arrangements of the ship, to the absence of any proper system for their care, and to the fact that the stalls were not

\* The italics are ours.

\* See footnote p. 256.

† Report of the General Officer Commanding, Cape Colony, C. of E. Rem., Q. 6024.

‡ Report of the General Officer Commanding, Cape Colony, C. of E. Rem., Q. 6005.

once 'mucked out' during the six weeks of the voyage."\*

The report on this ship gave rise to considerable War Office correspondence with South Africa, and the General at the Cape, after referring to the satisfactory condition of the horses when inspected at Cape Town by his Staff Officer, reported, "there is every reason to believe that the subsequent loss of condition in the animals was due to bad weather at sea between this port [Cape Town] and Durban, and possibly to the effects of the weather when lying off that harbour.† The whole of this correspondence was produced and placed before the Court. Yet the opinion they have recorded on this case, in paras: 116 and 176, is that the horses were starved and neglected, so that two-thirds were unfit for service for two months. The Court adds that they were in charge of a Civil Veterinary Surgeon, who was incapable, and that the stalls had not been cleaned out during the voyage. No mention is made of the satisfactory condition of the horses when inspected at Cape Town a week earlier, nor of the bad weather between that port and Durban, nor of the ship being kept outside for two days in a gale.

It is little short of extraordinary that a Court specially charged to investigate this matter does not refer to the incomprehensible action of the naval and military authorities in keeping this vessel outside the harbour at Durban for two days, instead of at once unloading her, though the seriousness of such action is obvious. We contend that this, and the fact of the satisfactory inspection of the horses at Cape Town, together with the opinion of the General Officer at Cape Colony, should have found a place in their Report. Nevertheless, these facts, in the opinion of the Quarter Master General War Office, "changed the whole aspect of the case." (Q.6004). The Court also was aware that the non-cleaning out of the stalls was due to the instruction of the Remount Officer at New Orleans, but in the face of this, the entire blame for the "Monterey" is centred in the Civil Veterinary Surgeon.

Unfortunately he seriously prejudiced his position by being found "drunk and incapable" (Q.2832) in his cabin on the vessel being brought into the harbour at Durban. He was seen in this condition by two officers, so that, to our shame, the fact is established.

It would have been a gracious act on the part of the Court to have mentioned the favourable reports received on this Transport Veterinary Surgeon, as they did in the case of the Remount Officer removed from his position by the Secretary of State (Report, para.95).‡ It was before the Court that the Remount Officer at New Orleans had stated to the Inspector General of Remounts (Q.5999) that the Transport Veterinary Surgeon of the

"Monterey" was a competent and hard working man, specially selected for the position, and that the Captain of the vessel had stated he had never seen a man work harder during the voyage, and that he was "never intoxicated except upon the regrettable occasion mentioned."

It would also have been just to the veterinary profession in this country to have stated that neither of the Transport Veterinary Surgeons mentioned above held a British qualification, and that both were foreigners.

The Court, in their Report, para.176, sum up their opinion on the "Knight Bachelor" and "Monterey" as follows:—

"With reference to the particular cases of the s.s. "Monterey" and "Knight Bachelor," the primary cause of the starved and neglected condition of the horses was clearly the absence of a conducting officer. In both instances the Veterinary Surgeon was incapable, and it does not seem that the master of the ship considered that he had any responsibility in the matter. The attendants were the servants of the ship owners, and were under the command of the master, and as there was no conducting officer on board, the entire responsibility for the safety and well being of the cargo fell upon the master."\*

We have placed before the reader all the facts of both these cases, and he must judge how far these warrant the conclusion drawn by the Court of Enquiry. The opinion given of the responsibility of the master relieves both Veterinary Surgeons of the charge of starvation and neglect. Nevertheless, in spite of this declaration, the Court, in para.182, were of opinion that "written instructions should have been given to the civilian Veterinary Surgeons, who, in certain cases, were in sole charge of horses on the ship."† It is difficult to reconcile these differences of opinion.

Of the alleged professional incapacity no evidence is adduced, while, if mortality be taken as the index, it is, especially in the case of the "Monterey," entirely in their favour.

Nor can we help remarking on the freedom of language employed by the Court in describing these men, as compared with the moderated tone adopted in dealing with Military Officers. With these incompetence becomes "unsuitable" (para.163), or "desirable to withdraw" (para.95); inefficiency is described as "a weak point" (para.225). Even the astonishing "Cervona" case becomes one of "a peculiar nature" (para.125), and the officer is merely described as "unsatisfactory" (para.182).

There is a third transport case to be dealt with. It did not find a place in the Report of the Court, but there is a great deal about it in the Evidence volume, which requires explaining.

The "Ripplingham Grange," a ship engaged by the Agents of the Inspector General of Remounts, left Sydney on 12th June, 1900, with 1085 horses in charge of a Colonial Veterinary Surgeon, there being no conducting officer. The vessel arrived at Durban on 14th July, after a very bad passage (Q.6030), and, instead of disembarking her weary

\* Report of General Officer Commanding, Cape Colony, C. of E. Rem., Q.6005.

† Report of General Officer Commanding, Cape Colony, C. of E. Rem., Q.6024.

‡ This History, p.257.

\* The italics are ours.

† " " "

horses at once, she was kept outside the harbour for six days in a gale (Q. 6025), during which time she could never have ceased rolling. The Agents at Durban apprised the War Office by cable of the unfair strain to which these wretched animals were needlessly exposed (Q. 5538), and under cable instructions from the War Office (Q. 5540), she was brought in and her horses unloaded. Such are the facts of the case.

When the Assistant Inspector of Remounts boarded the vessel in Durban Harbour, he found, according to his report (Q. 2900), that 140 animals had died out of 1005 embarked, and that many were so debilitated that some 20 had to be destroyed on board. The balance was stated to be in such "a shocking state of debility" that they would be unfit for duty for many weeks. Later (Q. 2902), the same witness placed the period of inefficiency at six months, but he apparently had no notes to guide him, and even with notes, his evidence on other matters was remarkable for inaccuracies; for instance,—1085 horses embarked, and not 1005, as stated by him, while the deaths were 104, and not 140.\*

The Remount Officer in Australia was communicated with, and his opinion was that the Transport "Veterinary Surgeon turned out very badly" (Q. 7555), but no reason for this opinion was given. When the Assistant Inspector of Remounts, Natal, was pressed (Q. 2905) as to the condition of the horses being the result of the effects of the voyage rather than of neglect, his reply was, "that I cannot tell . . . they told me they had had a very bad voyage."

The Quartermaster-General and Remount Authorities at the War Office, 7000 miles away, were, however, satisfied that the rough weather and "other causes" accounted for the condition of the horses landed. The "other causes" are not specified, but, clearly, they indicate the detention of this vessel, anchored in the open sea for a week during a gale and ceaselessly rolling. The only wonder is that she did not lose more than 9.8% of her horses. The fittings did not give way, and the deaths were caused by "absolute exhaustion" (Q. 6035).

The Court of Enquiry does not refer to this case, which reflects so gravely on the Naval and Military Authorities at Durban. In common fairness, the charge made against the Veterinary Surgeon in Q. 7555 should either have been substantiated or withdrawn. We regret to notice a willingness to find especial fault with the few ships which came over with Veterinary Surgeons said to be acting as conducting officers. For example,—the Assistant Inspector of Remounts, Natal, in Q. 2828, in speaking of some ships arriving without either a conducting officer or Veterinary Surgeon on board, stated that even if there was one of the latter, "he was probably a man not worth anything," and we have met with

this elsewhere, notably in Q. 6044. The Assistant Inspector of Remounts, S.A., in his report on the relative advantages of sending Remounts by "troop transport" or "freight transport," referred to the "gross neglect and inefficiency," in some instances, of the Civil Veterinary Surgeons and others in charge of animals from North America and Australia.° By the term "others," it is assumed conducting officers are intended. This ought, we think, to have been made clear, and not only the Transport Veterinary Service indicted. That there were conducting officers who failed is stated in the evidence of the Inspector General of Remounts.† He further added, he had recommended their services to be dispensed with, and that in some cases higher authority had deprived them of their medals and gratuity.

In the face of this evidence it is difficult to understand how the C. of E. Rem. could state that "the only conducting officer‡ whose management was reported to be unsatisfactory was the officer in charge of the 'Cervona.'" This reproach is very mild as compared with the stigma applied to the Transport Veterinary Surgeons.

#### LOSSES AT SEA.

The total number of horses which embarked from all ports for South Africa during the war is given as 352,353, of which 13,144 died or were destroyed on the passage.°° This loss represents 3.73%, but these figures are vitiated in one respect, inasmuch as the losses at sea include, in some cases, the losses prior to embarkation. The total number of mules embarked was 105,491, of which 2816 died or were destroyed at sea, or a loss of 2.67%. These numbers also are not strictly correct, from the cause above named. Nevertheless, the table is important as it covers the whole period of the war.

There are several other tables. One is in Appendix 38a of the Royal Commission, which covers the entire period of the war, though it does not include the Yeomanry horses. There are several in the Evidence volume of the C. of E. Rem., pp. 210, 326, and some in Parliamentary Papers, Cd. 963, pp. 30-32, but these only cover a part of the war, or for broken periods, or from certain ports only, and are compiled from data which do not admit of comparisons being made. There are also discrepancies among tables which should agree. We have thought it best for the present purpose to neglect all of these excepting Appendix 38a, and Parliamentary Paper Cd. 963. The latter covers the period from the outbreak of war to 31st December, 1901, or five months short of the full time. It is evident that all the tables are either incomplete for the full war period, or wanting in rigid exactitude, so that the results can only be taken as a close approximation to the truth.

† For other inaccuracies in this witness's evidence, see C. of E. Rem., Q. 2829 and 3559; 2830 and 3519; 2816 and 3488; 2904 and 6035; 3619, 3622, 3647, 3653, 3656, 3659, also p. 293, "Evidence Volume."

† C. of E. Rem., Q. 1824.

‡ The italics are ours.

°° R.C. Appendix No. 38, p. 258.

A more important matter than the mean loss at sea, is that of the losses from each country. These, with the above qualification of being mixed up, in some cases, with the losses prior to embarkation, are given in the following table compiled from Appendix 38a. The mean given is that of the series of percentages in the table; this is rather higher than it would have been had the tables themselves afforded the needful data for re-calculation.

PERCENTAGE OF LOSS ON THE VOYAGE.  
OCT., 1899, TO JUNE, 1902.

	Horses with Units and Remounts.	Mules.
United Kingdom	6.04	—
Australasia	3.83	—
Canada	3.22	—
United States	2.48	2.00
Austria	1.62	—
Argentina	.64	—
Spain	—	3.06
Italy	—	.39

The number of animals on which this information is based is:—

Horses 307,400      Mules 103,760

In the following table, extracted from Cd. 963, the percentage of loss at sea of Remount horses and mules from different countries is shown for the first two years of the war. It will be observed that this table does not include horses with troops.

PERCENTAGE OF REMOUNT HORSES AND MULES  
LOST ON VOYAGE, 1ST SEPT., 1899, TO 31ST DEC., 1901.

	Horses.	Mules.
United Kingdom	6.34	—
Canada	4.05	—
United States	3.21	2.68
Australia	3.16	—
Austria	2.07	—
India	1.96	.2
Argentina	.74	—
Spain	—	2.71
Italy	—	.54

The number of animals on which this table is based is:—

Horses 206,063      Mules 91,769.

[A good example of discrepancy in official tables is afforded by the figures for mules from Italy and Spain, which, in both of the above tables, should have agreed. In the first table, 7003 mules are shown as purchased in Italy, and 15,231 in Spain. In the second table, 5102 mules appear as purchased in Italy, and 18,543 in Spain, the purchasing period in each table being identical. The first table is the more accurate.]

It has been generally believed that a great deal of the loss at sea was due to the horses being carried from high and cold latitudes to hot southern latitudes, and that where no such seasonal differences occurred the resulting loss was small, as, for example, in the case of the animals shipped

from the Argentine. To investigate this point we shall group the above tables into countries north and south of the Equator.

NORTH OF THE EQUATOR.

	Horses : *	Death Rate.
United Kingdom	6.04	6.34
Canada	3.22	4.05
United States	2.48	3.21
Austria	1.62	2.07

SOUTH OF THE EQUATOR.

	Horses :	Death Rate.
Australasia	3.83	3.16
Argentina	.64	.74

The supposed advantage of a ship not having to cross the Equator is not borne out by this table. The losses from Australia may be taken as about equal to the losses from Canada; while those from the United States, and certainly those from the Mediterranean, are less than the Australasian rate. The small Argentine loss may be explained by the fact that the trade did not last long, and the large majority of the ships ran during the most favourable time of the year for a good passage.† Further, it was only a short journey. A long and tempestuous passage, such as is frequent in Australasian waters, or those of the United Kingdom, are the two chief enemies of horses at sea.

The United Kingdom stands at the head of all countries in affording the highest loss on board ship; in this case the figures represent the actual loss at sea, for they are not vitiated by being burdened by the loss prior to embarkation. Nowhere, perhaps, was greater care shown in the selection and fitting of ships, or in inspection prior to embarkation, yet the results were bad. Among groups for broken periods—which we have hitherto avoided referring to—the results are even worse than the mean table presents; for example: among 2300 remount horses despatched in the winter months of 1899, the loss was 7.45%, and among 26,860 remounts which embarked in 1901, the loss was as high as 7.95%.‡ In connection with this, two causes are very evident, *i.e.*, the character of the weather around our islands, and the unfortunate practice which prevailed of the same vessel touching at two or three ports in the Kingdom for her complement of horses before starting on her voyage. This was an important contributing cause. We shall quote authoritative evidence on this point. Mr. S. J. Graff, Assistant Director of Transports at the Admiralty, in his evidence before the C. of E. Rem., Q. 6144, made the following statement:—

“In the case of five ships which have carried horses, both from England and Fiume, under precisely similar

\* No mules were purchased oversea south of the Equator.

† The route Buenos Ayres to Cape Town is in the neighbourhood of the parallel of 40° S., which will take the ship in the region of permanent westerly winds with a moderate sea. The journey is regarded as a fine weather voyage, in which the wind and sea are astern.

‡ See Cd. 963.

arrangements as to fittings, etc., it will be seen [from tables he handed in] that while the average loss from the United Kingdom was 9.23%, the losses in the same ships, when carrying horses from Fiume, were .97%. The conclusion seems to me inevitable that the fault does not lie with the ships, but must be sought in other causes, and I venture to suggest that the practice of making every ship embark horses at three United Kingdom ports [London, Southampton and Queenstown], whereby the voyage is prolonged four days in its most trying part, must have something to do with the adverse results."

We entirely agree with the conclusions of the Assistant Director of Transports at the Admiralty, not only on account of the loss of time and additional bad weather, but, chiefly, the air stagnation which occurs the moment a vessel ceases to move through the water. Every hour that a ship, with horses on board, is not on the move is a serious matter, as the ventilation is at a standstill. The influences of the time of year on embarkation in this country are shown by a table put in by Mr. Graff—"B," p. 210, C. of E. Rem., prepared for the year 1901. The horses embarked in the United Kingdom during the first quarter gave a death rate at sea of 8.77%. During the Midsummer quarter the rate rose to 10.23%; during the Michaelmas quarter it was 7.22%, and the Christmas quarter 8.98%. It is true that an equal number of animals were not embarked each quarter, but for the first three quarters they were near enough for comparison. The Midsummer quarter comes out the worst, so that the effect of snow, rain, or cold wind, at date of embarkation, is not evident. We must look to the delay in getting to sea as one of the chief, if not the chief, causes of the higher death rate among animals shipped from this country. It is equally apparent in those troop ships which, through not being ready before the horses arrived, had to complete their fittings after the animals were on board, during which time, from personal experience, we can vouch for sickness having broken out in the few hours which elapsed before the ship was able to leave port.

The death-rate at sea was so alarming that greater inducements were offered to secure more efficient veterinary charge, by offering better remuneration; not only was there to be a fixed fee for the voyage, but a sliding scale of bonus per head depending upon the number of animals landed in good condition.\*

These improved terms did not become operative until September, 1901, but they led to, or were associated with, a marked diminution of loss in the North American passage, as may be seen in the following table:—

\* The terms were £50 for the voyage, with the usual first class passage back, and out-of-pocket expense; there was also detention allowances in Africa while waiting for a ship. The sliding scale of bonus was three shillings per head landed, for a voyage mortality under 2½%; a two shilling bonus where the death rate was under 5%; a shilling bonus with a loss less than 7%; and no bonus if the loss was 7% and over.

	NEW ORLEANS.	Percentage
	Horses embarked.	lost.
Apr., 1900—Mar., 1901	36,000	4.67
" 1901 " 1902	62,400	2.34*
" 1902—June, 1902	10,000	1.55

	NEW ORLEANS.	Percentage
	Mules embarked.	lost.
Apr., 1900—Mar., 1901	33,900	2.99
" 1901 " 1902	25,400	1.08*
" 1902—June, 1902	3,700	.70

There is no evidence of the effect of improved remuneration in the embarkation from the United Kingdom, excepting during the brief period April to June, 1902, as may be seen from the following table:—†

	UNITED KINGDOM.	Percentage
	Horses embarked.	lost.
Apr., 1900—Mar., 1901	19,900	5.52
" 1901 " 1902	32,000	7.48
" 1902—June, 1902	6,600	3.60

There can be no doubt that in all cases the whole of the animals proceeding on any given vessel should be embarked at one port and immediately sent to sea.

The mean death rate of 2.67% for mules at sea is higher than one would have expected, for they are more placid and better sailors than the horse. The highest death-rate, furnished by the United States in 1899 (4.11%), is now well known to have been due to overcrowding. The mules shipped from Spain in 1900 also did badly (3.34%); how far that was due to the alleged maltreatment they received before embarkation‡ and how much to over-

\* From a return on p. 319, C. of E. Rem., the improvement in the death rate dates from May, 1901, four months before the extra remuneration came into force.

† It is not permissible to compare a three months' period with a twelve months', but we can compare it with the quarterly rate given in the Graff tables above, for the corresponding period of the previous year, and the improvement is there very marked—3.6% as against 10.23%.

‡ The alleged neglect of the Spanish mules awaiting embarkation at Gibraltar was brought to the notice of the Remount Authorities in London, and the Remount Officers in Spain, by Mr. H. Sessions, F.R.C.V.S., who was sent to Gibraltar to mallein the mules before embarkation. His correspondence was produced before the Court of Enquiry, and we extract portions of it from the examination of one of the witnesses. All his letters were addressed to London, and the one in Q. 3370 also to the Remount Officer at Madrid.

Q. 3196. "I found when I came here [2nd April] a state of perfect chaos, the most elementary conditions of animal hygiene neglected, the animals waiting for the ships unable to lie down, their rations erratic and extraordinary, picking up bran mashes on wet days out of open air gutters. . . ."

Q. 3320. 16th April. "I have had all the mules lying down this week. They seemed very grateful for it, and took full advantage of the rest. Previously all mules through here have had to stand all the time. I have also got them fed three times a day instead of twice, and some rough mangers are being put up. . . . The 88 that came in to-day were going to be tied up to ropes in the open and let feed off the ground. It is very wet and cold, and some

crowding and other causes, cannot in the absence of complete evidence be stated. Fortunately, however, we are not left entirely ignorant, as two ships carrying mules from Spain are specially included in a return shown in Appendix C, p. 329, C. of E. Rem. Each vessel lost over 18% of her animals, from influenza in one case, bad weather and the giving way of ship's fittings in the other. Another ship was detained for three days in Gibraltar Bay "under a roasting sun" waiting for wholesome instead of "filthy brackish" water, and more forage as she had an insufficient supply on board for her animals. See C. of E. Rem., Q. 3272. It is not surprising to learn from the table on p. 320, C. of E. Rem., that she lost 50 animals or 5%. In the same table it will be seen that two other vessels from Spain lost 6%, one 5%, and two others 4% of their animals, though unfortunately the causes are not stated. The Spanish mule is not a bad sailor. Three vessels which left Spain in 1899 lost .14, .36 and 1.77 of its mules respectively, while a fourth, carrying 2249 mules, the largest number of animals on any one vessel during the war, reached Cape Town with a loss of .44%.

they had out were in a bad mess, so I protested and got them under cover."

Q. 3304. 18th April. "I have been in a state of constant and friendly war with many officers, as I think the way the mules are treated is most inhuman and scandalous. After their long train journey, I found this morning that they were tied up so that they could not lie down, although with care they might all have had room to do so. There are another lot of mangers up, enough for a couple of hundred more mules. This will be better than their hunting in the mud for their barley." [It was a two or three days' journey by rail to Gibraltar, during which time the animals were neither watered nor fed.]

Q. 3305. 19th April. "I have tried to get better arrangements made to meet the mules here [San Roque, 7 or 8 miles from Gibraltar], and not to allow them to be left in the train for 12 or 24 hours after arrival."

Q. 3308. 27th April. "You will be glad to hear that the last lot of mules from Madrid were safely stabled by 6 o'clock on Wednesday in very fair condition, instead of being left in the trucks until Thursday, and unfed and unwatered until the middle of the day. . . ."

Q. 3315, 3370. 1st May. "I have very much worried Colonel —, and others." "I got Colonel — on Saturday, and the Governor on Monday, to come and see for themselves the lack of accommodation and muddle in which the mules are. Now orders are out for more room, more mangers, more attention, and I am trying to get all the animals a few days' good food and rest before embarkation, and then to work some more into better stables."

Q. 3317. 6th May. "Only last week I found that for five days the mules had nothing but bran and straw, and as many were out in the open eating out of 'gutters,' a good deal of the little nourishment they ought to get went down the drains. I brought Colonel — down to see it. I was told that the bran was given by orders from the War Office: but I hunted up the Regulation and found it had been misinterpreted. . . ."

Q. 3318. 16th May. "I am glad Colonel Maude came down here, as, about a week ago, I had written to Colonel — a rather strong letter, as I could not get him to finish some work he had promised to get done, and I had asked him to put it before the Governor. I think Colonel Maude thought I was 'right.'"

It is only fair to say that the statements made in the correspondence quoted in the footnote were practically denied, and it is unfortunate that Mr. Sessions was not called as a witness by the Court.

The Court, in paragraph 47 of their Report, deal with the care of Spanish mules in 1900 as follows:—

"Letters were produced showing that a civil veterinary surgeon who was sent from England to Gibraltar to test the mules for glanders, made adverse reports to Colonel — at Madrid regarding the want of accommodation and the inadequate arrangements at that place [Gibraltar], but that officer did not communicate these reports either to the Inspector-General of Remounts at the War Office or to the Chief Staff Officer at Gibraltar."

Nevertheless, the correspondence quoted above shows that, notwithstanding Col. — action, the Remount Authorities in London, and the Military Authorities at Gibraltar, were acquainted with the case, and that the Governor saw the mules, see Q. 3315, 3370. The Governor of Gibraltar at this time was subsequently the President of the Court of Enquiry Remounts, and had that portion of Mr. Sessions' statement which referred to the Governor's visit been incorrect, he could hardly have refrained from so saying.

The opinion of the Court is contained in para. 170 of their Report:

"As to the arrangements made at Gibraltar for the accommodation of mules, the evidence is somewhat conflicting, but although grounds for complaint probably did exist, especially when large numbers of mules had to be detained there for several days, the Court considers that such causes of complaint as were brought to the notice of the Authorities, were remedied as far as local conditions made it possible."

In connection with this opinion it is important to bear in mind that the complaints were made by a civil veterinary surgeon against the military authorities, and that, but for him, nothing would have been heard of them. His notes were made at the time, and there is a realism about them only too familiar to those who have seen the care given to animals on service. Though in para. 160 the Court states Colonel — did not communicate the Veterinary Surgeon's reports to the Authorities at Gibraltar, they admit in para. 170 that complaints were brought to the notice of the Gibraltar staff, and were as far as possible remedied. Mr. Sessions could have been called as a witness if the evidence had seriously been regarded as conflicting.

Mr. Sessions could hardly know that his procedure in writing to London, to the people who employed him, was irregular from a military point of view, and that all complaints should have been made in writing to the Authorities in Gibraltar, but this technical fault was due to his ignorance of official routine, and ought not in our opinion to have carried any weight in the interests of a public inquiry.

The Gibraltar episode is instructive; it furnishes us with an example of a Civil Veterinary Surgeon

endeavouring, without a knowledge of Army routine, to bring the neglect of animals to the notice of the Authorities. He had no status or position; he was sent to Gibraltar to mallein mules, and not to find fault with the conditions under which they were living prior to embarkation. The mouthpiece for such official representation was at Madrid, 400 miles away, and *via* Madrid it must come to the local authorities at the Fortress, if it is to be regarded as official. Mr. Sessions, with no knowledge of official circumlocution, attempted on the grounds of humanity and efficiency, to improve the condition under which the mules collecting at Gibraltar were living. In the first instance he wrote to the War Office, to the people who sent him out. He begins his letter, which is published in full in C. of E. Rem., Q. 3041, by saying that he "took the liberty" of preventing a glandered mule being embarked, and that it was due to the courtesy of the embarking officer that his wishes in this respect were observed. He states that he had no *locus standi* or authority to act, and desired that instructions should be sent to Gibraltar to have him recognised in the matter of the well-being and care of the mules. He even asked the War Office for authority to spend the needful money in getting the animals shod. He begs that he may be informed whether "the officer with the boat" [Military Conducting Officer?] is the final authority as to whether certain mules should be accepted or rejected at embarkation, for as matters stand, he says, he has no position and cannot speak with authority.

In one of his last letters from Gibraltar, where he was being relieved by another civil veterinary surgeon, he asks the War Office that the powers delegated to him [to do the best he could for the mules, to requisition whatever was wanted, and to pay for anything needful] should be transferred to his successor, and concludes by saying that unless the latter receives strong support, "official routine will prevent his doing much for the mules, and they badly require daily attention."

His powers were transferred to his successor, which is evidence, if any were required, that his representations were necessary. He increased efficiency, he saved unnecessary suffering, he took the initiative, he "worried" the local authorities until attention had to be paid to the representations of a man who was not in accredited veterinary charge, but, nevertheless, not one word of commendation escapes the Court of Enquiry Remounts for the measures he adopted, or for the initiative he showed.\* This is the more to be regretted when one remembers the severity of their judgment in the case of those foreign Transport Veterinary Surgeons whose chief cause of failure, as we have seen, was due to want of initiative and adherence to a bad system. We have little doubt that had Mr. Sessions, in the same way as the foreign Veterinarians on the Trans-

ports, accepted matters as he found them, he would have received the blame for the condition of the mules at Gibraltar, and the subsequent losses.

Mr. Sessions is unfortunately dead, but his correspondence, published in the Court of Enquiry Remounts, shows the remarkable efforts he made to bring his professional knowledge to bear in the interests of the public. We consider that these services should have received the recognition of the Court in their subsequent report, in which, it is observed, he is not even referred to by name.

In the Court of Enquiry Remounts is a table (Appendix C, p. 329), showing the ships with horses and mules where a death rate exceeding 10% occurred; the table is up to 31st December, 1901.

Four vessels were wrecked or stranded, in two cases losing nearly the whole of the horses. Six vessels sustained heavy loss through bad weather, in three instances the fittings giving way. On eleven vessels the excessive mortality was due to disease: influenza, pneumonia, strangles, mange and glanders; on four vessels the mortality was due to defective ventilation, heat apoplexy and suffocation; one ship alone losing 24% of her horses from this cause. In several instances the cause of the loss is not given. It will be borne in mind that the above list is only for vessels with over 10% loss; this excludes many where the mortality was nevertheless considerable.

Respecting bad weather and defective fittings, the typical case is the "Rapidan," which left Liverpool with troops and horses in the early days of the war. The Veterinary Officer (Captain Blenkinsop) complained about the flimsy nature of part of the fittings before the vessel sailed, but the Naval Authorities decided she must proceed.\* It is doubtful whether they attached any importance to the objections which, fortunately, were given in writing.

The "Rapidan" left Liverpool on 1st November, 1899, with 484 horses on board. Heavy weather was encountered on the 3rd, and at the same time a fire broke out in the engine room. The engines had to be slowed down and the vessel lay rolling in the trough of the sea. The horses could not obtain a proper foothold, for the battens were too far apart, further, the whole of the concrete surface of the deck was not covered by a wooden floor, and on this the feet could get no grip. The horses slipped up or fell, either forcing the parting bars out of the weak slot in which they were placed, (see pp. 253, 254), or lifting them out of the groove in their efforts to regain their feet. The parting bars now lay as loose planks under the horses' feet and between their legs, the floor battens, already imperfect, were rendered useless, and with every roll the animals either fell or were shot forward against the breast bar. [Some were subsequently found wedged between the stanchions, which had to be sawn away to liberate them]. The strain on the

\* The Court commended or spoke favourably of individuals in the following paragraphs of their Report:—59, 95, 130, 155, 161, 164, 219, 237, 238, 240, so there was a precedent.

\* The parts to which the greatest exception was taken, were the nailed on weak fillets which formed the slots into which the parting boards dropped.

#### IV. PACK TRANSPORT CROSSING SPRUIT.

This photograph is a good object lesson. Note the massive chest on the nearest mule; there is no such pattern in the service, it has evidently been removed from a Boer farm, and when empty is almost a mule load in itself. The rear pack-mule is carrying a service load on the off and an unauthorised load on the near side. The weight of the latter has pulled the saddle over against the withers. The whole load has also worked back, and the near side chest must be wearing a hole in the hip. These are points which would be at once noticed by a good transport officer.

*Photo by Mr F. B. Gresham.*

#### V. BRANDING OXEN.

#### VI. DIPPING BATH FOR THE TREATMENT OF MANGE.

The animals walk along a narrow passage in which they cannot possibly turn; the pressure from behind keeps all in front on the move. There is a sudden drop of six feet just in front of where the leading animal is putting down the off fore, and the next step will find him over his head in the water. There are several yards to be covered by swimming before the landing place is reached.

**I. RAILWAY TRANSPORT.**

Illustrates the difficulties of watering and feeding horses in trucks. The photograph shows a column being moved by rail.

*Taken by Mr. F. B. Gresham, of Newark, late C.V.S.*

**II. STUCK IN A DRIFT.**

An example of a moderate road and a heavy load. Double spans of oxen are in use.

**III. MULE TRANSPORT CLIMBING THE BANK OF A SPRUIT.**

An attempt has been made to improve the road, and the mules may just be seen on the other side of the working party.

*Taken by Mr. F. B. Gresham.*

stanchions was now so great that they "started," and the remaining parting bars then fell out. The projecting French nails used for the fillets produced severe injury. Some horses were kicked to death by their neighbours, others had their necks broken by the halter, or were suffocated by the nose-band pressing on the nostrils as they lay suspended by the head ropes, or had their lives battered out of them. It was impossible to render much assistance; most of the men were sick, while the nails in the boots of those who could get about, gave no grip on the iron-sheathed decks.

As the result of this disaster 166 horses were killed outright or had to be destroyed, over 34 %, and the ship, being once more got under steam, put back to Liverpool with her terribly battered animals. There were wounds on the survivors extending from shoulder to knee, and from hip to foot, and 109 of the worst injured were there put ashore.

The fittings were now strengthened; the slots for the parting bars were made deeper, screws being employed for the fillets instead of nails; the deck under the horses' feet was covered, and a central batten added. On the second voyage they again had bad weather, but no further mishap.

The "Rapidan" was frequently referred to in the C. of E. Rem., and the evidence of the Naval expert (Q, 5401) was to the effect that during the gale a fire broke out in the engine room, and the engines were stopped; the ship not being under control opened out in the trough of the sea, and, as a result, the parting boards of something like 100 horses dropped out, the uprights and everything else remaining. We can offer no expert opinion on the ability of a ship to increase its width without the external plates opening out and the vessel going to the bottom; but it is certain that in the case of the "Rapidan" her parting boards fell out from the causes we have named.\* It was an accident that never ought to have happened, and had the veterinary objections been given attention to by the Admiralty Officials, there seems no reason why the fittings in a vessel lying in the trough of the sea should give way. The work of fitting was done in a hurry, and the ship was not completed even at the time the horses were filing on board; workmen were still on the vessel when she dropped down the Mersey.

Too much is left to the discretion of Naval Officers, † excellent men, but necessarily without

\* Since the above was written, I have been able to obtain expert opinion on the question of the sides of a vessel opening out, and it is to the effect that it is neither possible nor imaginable without destruction of the ship. There is considerable longitudinal strain, which leads to perceptible movement, but any lateral opening could only be due to elastic strain in the beams, and the want of perfection in rivetted joints; it would be less than the eighth of an inch. This ship would have had to open three inches laterally to allow the parting boards on both sides to drop out.

† In December, 1902, when the Expedition was being sent to Somaliland, the diet scale for animals shipped at Cape Town was framed as follows by the Naval Transport

much experience of horses, and none of the violence and strength exhibited by animals in a state of panic. There should always be an experienced Veterinary Officer at the port of embarkation as part of the Transport Staff.\* An equally important matter in horse ships is proper ballasting. The "Rapidan," and many others, were light and stood far too high out of the water, so that in a cross sea they rolled badly.

In the matter of outbreaks of disease, it is evident that the most rigid inspection before embarkation will not detect a case of strangles in its incubative period, nor can the subject of pneumonia be anticipated. Among remount horses influenza, strangles and pneumonia were the most common causes of illness, and with mature horses a disease simulating influenza, together with pneumonia, were the chief causes of loss.

In the following table the cause of death occurring among many thousands of animals shipped is given separately for the United Kingdom and the United States:—

	UNITED KINGDOM. Deaths 2028.† Per cent. to total deaths.	UNITED STATES. Deaths 1245. Per cent. to total deaths.
Pneumonia	60 %	60 %
Strangles	5	5
Gastro-Enteritis	3.2	7
Influenza	2.9	4.5
Apoplexy	2.5	7
Purpura	1.7	8
Septicæmia	1.2	?
Glanders and Farcy	.29	5
Various	25.00	?

It is curious to observe that from both countries, among the fatal cases, the deaths from pneumonia and strangles were identical. Pneumonia furnished by far the largest percentage of deaths.

Ship pneumonia is, as we have seen, the most common cause of death, and its study ought to be taken up. It does not differ materially from the same affection seen ashore, excepting its extreme rapidity and fatal character. In all cases examined post mortem by the writer the lungs were found in

Authority, no reference being made to the Veterinary Service:—

Each horse daily 1 to 2 pints of vinegar,  
½ to 1 lb. of salt!  
½ to 1 lb. of nitre!  
4 lbs. of oats,  
5½ lbs. of linseed.

In December, 1902, the Naval Transport Department had been shipping horses continuously for three years!

\* A ship was passed by the Admiralty Transport Officer at Liverpool for 740 horses which could only carry 700. He had included the hatchways as deck space, so that the horses below would have been hermetically sealed. Forty-three horses subsequently died on this ship from pneumonia. C. of E. Rem., Q. 6127.

† These deaths occurred among 30,900 horses. The numbers furnishing the deaths in the United States table are unknown, but probably 50,000, and include both horses and mules.

a necrotic condition. Some horses are attacked a few hours after starting, but, as a rule, each day produces its crop of fresh infections. On board a ship is a good place to study the question of contagiousness, but in our opinion it was not evident. It seems impossible to escape from the conclusion that foul and stagnant air are the exciting causes.

Overcrowding is best illustrated by a ship, the "Manchester City" (see footnote, p. 253) which left New Orleans in November, 1899, with 2090 mules on board. It took three days to load the ship. Abnormally hot weather was met with in the Caribbean Sea; there was a stay at St. Lucia of 47 hours during intense heat and no air movement; after the ship had been 35 or 36 days at sea it arrived in South Africa, 187 mules having died. The spare places in this vessel were taken up with hay and fodder; the ship's ventilation was also obstructed by forage, and the animals closely packed.\* The weather was unusually hot, a temperature as high as 115° being registered between decks, and it rarely fell below 100° to 98° while passing through the hot belt. On 6th day after leaving eleven animals died, up to this time the deaths had been four or five a day. There were eleven deaths the next day; on the 8th day out the vessel had to lay-to for repairs, and eighteen animals died. She anchored at St. Lucia for 48 hours, and in those few hours 51 mules died. The day after leaving St. Lucia she lost 23, and from that time onward the mortality decreased as the weather became cooler, and the cubic space resulting from deaths and consumption of forage increased. The atmosphere below in which these animals lived was so foul, that the men employed looking after them would not work more than half-an-hour before coming on deck for air. The absolute blackness, excepting for a few electric lights, intensified the evil. At St. Lucia there was neither air nor water movement, so that even the dead animals thrown overboard had to be towed away. This created considerable delay in disposing of the dead still on the ship, which, in such a temperature rapidly became putrid, even their hoofs came off before they could be thrown overboard! Such a condition assists in realising the state of the atmosphere between decks. This vessel was a veritable "Black Hole," her losses were 7.96%. Another mule ship sailing from the same port a few days later than the "Manchester City"—the "Anselma de Larrinaga"—was also overcrowded, and lost 10.57% of her mules from pneumonia, suffocation, or heat apoplexy.

Bad weather, exclusive of pneumonia or the fittings giving way, may kill horses from exhaustion. It must be remembered that during the time the vessel is rolling the animals get neither rest nor

sleep. A vessel rarely pitches to the same degree that she rolls, and, moreover, the movement is slower excepting at the ends of the vessel. It is the rolling which works the evil, and to estimate what it means in the way of muscular and nervous strain it is only necessary to stand in the alley-way at the end of the horse deck and watch the pendulum-like movement of the body. As the ship rolls fifty heads looking towards the roll disappear at the same second of time, whilst the heads of the fifty neighbours opposite, who are looking away from the roll, appear with the same suddenness and precision. The roll in the opposite direction reverses the movement. The feet are the fixed points on which this swaying to and fro occurs. It is not difficult to understand the mortality which took place on the "Monterey" and "Ripplingham Grange," (pp. 258, 259), which were kept for two and six days respectively, rolling outside Durban Harbour, after a long sea voyage.

The cerebral cases, or so called "ship-staggers," are most puzzling. Some happen in bad weather, but they may also occur in harbour, when a high external temperature is associated with absence of air movement. Our knowledge of these cases is very imperfect. Some are, no doubt, reflex, especially those occurring in bad weather, and are due to inability to vomit; others are apoplectic in nature. In any case, a cold douche and fresh air work wonders.

A properly fitted dispensary and a centrally situated hospital are matters of great moment when much sickness prevails. The hospital should be isolated, placed midships, and on the main, or even upper deck. It must be accessible from all parts of the ship. A rule should be made to treat only the simplest cases in quarters. Horses can only be conveniently moved from one point of the ship to another when good large hatchways exist. A small hatchway means a very steep "brow," up which a sick case may be too feeble to climb.

It is easier to formulate improved regulations for long sea voyages than to have them given effect to. More air space is required, that means fewer animals should be carried. We sacrifice safety to numbers. It is no use carrying 600 animals if 50 are to die on the voyage; far better carry 550, and devote the space gained to improving the accommodation and comfort of the others. The air between decks must, by means of fans, be kept in a state of movement from the moment the horses enter the vessel until they leave it. The introduction of fresh air by windsails must not be wholly depended upon for air movement. A wide alley-way, along which exercise can be readily carried out, is absolutely essential; good fittings, more liberal feeding, absolute cleanliness of horse decks, and a proper system of drainage for the decks below water level, are all indicated.

Fifteen per cent. of the horses should be allowed to lie down daily; what this would mean in a long voyage is incalculable. The regulation allowance

\* A Clause in the Agreement was that the shipowners had the right to carry these animals as their own property irrespective of any regulations. They had fitted it up to carry 2349 animals, the Admiralty understood it could carry 2500, but only 2090 were permitted by the Remount Officer to embark.

of spare stalls is five per cent., but it does not contemplate these being turned into two boxes and bedded down with matting; nevertheless, in a month's voyage 60 % of the animals would in this way have secured one day's rest. Eight stalls for every seven animals would give each horse a rest once a week, and if that extra stall costs £15 it is well worth the money.

Prejudice dies hard. The old idea was that the hind shoes should be removed from horses before going aboard; the Veterinary Service before the war pointed out the disastrous results of such practice, and generally speaking its advice was followed.\* The opposite course was pursued with the usual results; the feet were broken away, and the animals useless on landing until the feet had grown sufficiently to carry nails. Horses, however, should not be embarked wearing shoes with calkings. Regular attention to the feet on board is a matter of supreme importance. A large number of horses cannot be embarked fully shod up; there must be many that require attention, and a daily proportion should come under the hands of the farrier for this purpose. The cold fitting of new shoes is not a simple matter, unless they be of the smallest sizes; in the majority of cases a "remove" suffices. Tools, nails and shoes of suitable sizes should be stored on board where they can easily be got at, and not put at the bottom of the vessel.

Mats may be employed for kickers, and there are none to equal the ordinary household article which can readily be suspended at the proper height.

Owing to the close proximity of horses on board ship, contagious and infectious diseases spread with great rapidity. Veterinary inspection at the time of embarkation cannot be too thorough, and all doubtful cases should be ruthlessly rejected.

The use of disinfectants on board ship is minimized by daily cleanliness; all those containing lime are objectionable owing to their action on the horn of the foot. One of the chief proprietary solutions served out during the war was found to be decomposed by sea water on dilution, and in consequence worthless.

The use of drugs on board should be prohibited, excepting under veterinary supervision. They are never needed on the wholesale lines that the laity wish for. Vinegar is worthless, nitre unnecessary, sulphate of magnesia useful under veterinary control. Nothing can take the place of sound management, the keynote of which is the inspection of every horse by the responsible authorities not less than three times a day, which includes an early morning and night visit.

The landing of horses on the almost unbroken coast-line of South Africa was a difficult problem. Cape Town possessed a harbour with limited accom-

modation; Port Elizabeth and East London were practically open roadsteads, and Durban, a port with a difficult bar. At Port Elizabeth the horses had to be slung over the side into lighters below, and tugged ashore. Remarkably little injury occurred as the result of these rough operations, once the system of employing canvas instead of rope slings was introduced, and the tying up of horses on the lighter adopted; prior to this they were loose, and naturally damaged each other.

Horses, after being a month at sea, land with big legs, tender feet, tired and weary. Their first essential is a rest, and their next, walking exercise. During the war, especially the earlier months, they usually hobbled direct from the boat to the train, and the inconvenience and suffering of a long land journey were added to those already experienced.

#### RAILWAY TRANSPORT.

The railways of South Africa are narrow gauge, 3 ft. 6 in., and single lines. The number of cattle trucks available was quite insufficient for the transport of the troops, and was supplemented by the ordinary open goods and coal trucks whose low freeboard was raised by a railing. The trucks in the Cape are short, but those in Natal are long and of iron, especially the coal trucks, which, in that colony, were almost exclusively used as horse trucks. In no pattern of truck did facilities exist for watering and feeding during the journey; with the covered-in cattle trucks it was impossible to do anything without taking the animals out; this was out of the question where speed was everything, and a single line congested. We are now mainly referring to the long journeys undertaken by troops just landed at the beginning of the campaign, who were being rushed up to the front as fast as trains could be obtained; it also applies to the train loads of Remounts being sent up at this time to replace casualties. In fact, it may be said that until about April, 1900, no system could be established for properly feeding and watering on route.

The animals were placed *across* the truck and tied with their heads to the side. The narrow trucks were too small for big horses, which were badly rubbed on the tail and quarters: on curves the animals lost their foot hold, and on inclines, especially those on the Natal railway, the mass in the long trucks gravitated towards the end and exercised extraordinary pressure on the lowest horses.\* Iron shoes on iron floors give no foot hold, and the sand used on the floors gravitated with the horses and played over the iron surface. The injuries occurring between Durban and Mooi River during the concentration on Colenso numbered hundreds, and many were fatal. They were not so numerous in Cape Colony, for the table land is fairly level, but, nevertheless, they represented a considerable degree of inefficiency. No tying up could enable horses to maintain their position; even if the head ropes held,

\* Nevertheless, the Assistant Inspector of Remounts S. A. states in his official report:—"Shoes should be taken off before embarkation: feet take less harm from expansion without shoes . . . it would be far better to ship all animals unshod, and obviate possible injury on shipboard and in landing." Parliamentary Paper, Cd. 963, p. 17.

\* See p. 87 for a fuller account.

the animals frequently fell, and, once down, could not rise. The Cape Government Railway never tie horses up in their trucks, and after a time we followed local practice with far better results. The animals now arranged themselves as far as possible parallel to the line of rail instead of across it, and were thus in a far sounder position to resist sharp curves and shocks in shunting.

It was urged by one witness examined before the Royal Commission (Q.13073), that the trucks used in South Africa should have been arranged on the principle employed for animal transport in India, *i.e.*, the horses placed parallel to the rails in two rows facing inwards, a bar across each batch, to which the heads are secured, and between the rows of heads a space for attendants and forage. By such a system horses can be watered and fed for days without detraining, and men are at hand to render assistance if any animal is in difficulties. This method leads to some loss of stowage-room, but that is more than compensated for by the better condition in which the animals travel, and attention to their requirements. Towards the end of the war some trucks were arranged on this system. It is impossible to over-rate the advantage such a method would have proved during the campaign in the alleviation of animal suffering. Day after day, in the early part of the war, troop and remount trains travelled with no chance of watering and feeding effectively. The truck with a roof and a jumble of frightened animals defeated all attempts at watering and feeding from outside, and to go inside with a bucket was impracticable. The roofless truck offered some advantage in this respect, for men could clamber along the woodwork frame, imperfectly water a few, and put nose bags on those they could reach\* (see Plate iii., Fig. 1). But watering by pails is slow and wasteful, and water was a valuable commodity that could only be obtained at long intervals, and in small quantities. With these trucks no other system was possible than that of detraining the whole of the animals and feeding them on the platform, a process out of all consideration with several trains on a single line, each waiting on the other, and urgency a matter of vital importance.

It was not until the first pressure of work was relaxed, with the advance from Bloemfontein, that it was possible to adopt some regular system with remount trains. Experience had shown that a party of men should accompany every train to assist horses in difficulties, and stopping places about 12 hours apart were arranged where the whole train load could be disembarked, watered and fed, by parties stationed at these roadside depots.

When the line through Natal became the main artery of Remount Supply a regular staging system was projected. The distance, Durban-Johannes-

burg, of 420 miles was divided into four stages; at each the animals were to be detrained and rested for 24 hours. This excellent system, under military pressure, was more honoured in the breach than in the observance, for four days could not be spared for getting animals to Johannesburg. It was carried out wherever possible. The Natal line probably furnished more injuries than that of the Cape, owing to the hilly nature of the country, and the long iron trucks. Horses must have a batten foot hold in a truck, as in a stall on board ship. An iron floor is a hopeless standing.

Projecting bolts were fruitful causes of injury, rough and careless shunting was a frequent source of accident, and steam whistles, sounding in close proximity to trucks, played their share in further upsetting frightened and nervous horses.

Innumerable representations were made by the Veterinary Service of the many injuries occurring in the train, and the military authorities were no less keen on reducing this source of horse wastage. The Railway Companies probably did their best under very trying circumstances, but it fell far short of what was necessary. One witness before the Court of Enquiry Remounts, a senior officer with many months' experience in the Remount Department, regarded the railway as one explanation of the great loss of horses (Q. 3807). He said the horses were occasionally hung up for days, and were treated very much as if they were trucks of coal. Trucks were sometimes detached from the trains without those in charge being informed, and the animals left behind in a siding with no one to look after them. From personal knowledge, we have known water denied horses at a station, as the supply for the engines would have been seriously affected, or, at least, that was the view of the Civil Engineer in charge of the section of the line. Want of sufficient water and food, sometimes an entire absence of both for two or more days, with animals alternately under a blazing sun and cold penetrating dew, rendered it no matter for surprise that trains arrived at their destination with the horses looking empty and worn, and trucks containing dead and dying. Especially was this so with remount trains conveying animals which had passed directly from ship to truck.

Horses which fell in the truck were rarely able to rise without assistance, and many in this way were trampled to death. Particularly was this the case with the debilitated animals returning from the Front, who were found, from experience, to be bad travellers. They had no strength left in their limbs to maintain a foot hold; with every sudden curve in the line and every shock in shunting they fell, and the dead were taken out sometimes by dozens, when the train arrived at its destination. Hundreds upon hundreds\* of these horses were destroyed at their destination, or before reaching it, as being unable to proceed further.

† Nose bags had to be left on until the next stopping place was reached; they were frequently lost, and if put on tightly to avoid this, the animal was partly asphyxiated through breathing foul, moist and heated air, for the canvas is impervious when wet.

\* It would be quite safe to say thousands, for we have known between two and three hundred destroyed from one large consignment.

During the course of this History we have seen how frequently the line of rail was used for strategical purposes. In the De Wet raid of January, 1901, in nine days, 89 troop trains were despatched from Bloemfontein to various parts of Cape Colony bordering on the Orange River, and while this was occurring 27 trains were bringing Bruce Hamilton from Winburg to Bloemfontein: No wonder that, under this pressure of work, animals got very little attention even when travelling with troops. Loaded up at night, starting at dawn, rushed through while daylight lasted and the line safe, left little time for care and attention. McKenzie-Rew\* tells us how, in the subsequent chase of De Wet back into the Free State, ten horses of the Warwick Mounted Infantry were placed in a hermetically closed truck [apparently the type used for carrying explosives† and when the door was subsequently opened they were all dead. The most ordinary care and intelligence would have saved the lives of these animals, at a time when every horse was required.

The most extensive strategical move by rail was that carried out between the 5th September and 11th October, 1901, when the troops were concentrating to repel Botha's invasion of Natal. No less than 32,836 animals were moved by rail. A derailed train caused the death of 25 horses and injured 30 others, but this was the only accident on a large scale. On the other hand, there was a considerable amount of suffering and inefficiency in other ways, for mange spread in a remarkable manner, due, of course, to the close contact in trucks.

When Bethune's column was sent to Zululand in July, 1901, the trucks containing the horses and men became detached, and the horses were left entirely to themselves, and many of the animals died from want of attention. †

The spread of disease through the agency of railway trucks was, doubtless, considerable. There was frequently no time nor appliances for cleaning them; their thorough disinfection in time of peace leaves much to be desired, in war, the pressure is too great and continuous. Nevertheless, the matter was not overlooked; the Railway authorities, both military and civil, did what was possible, and a marked improvement was evident in course of time. Administrative Veterinary Officers on the line had it as part of their duty to inspect trucks as opportunity offered, and make the needful representations. Labour was always a difficulty, and rolling stock cannot be kept idle at a time when every truck is required, and the flow up and down the line has to be equally maintained. Thorough disinfection is skilled work, this is frequently forgotten.

#### TRANSPORT IN THE FIELD.

It may be explained that the transport animals of an Army in the Field are invariably divided into three main groups. *The First Line Transport* is employed for ammunition and water carts, draught or pack mules for machine guns, and mules for technical equipment, such as signalling apparatus, Artillery, Engineer, Medical and Veterinary Stores. This transport is in the care of the regiments or units to which it is attached, and officers of the various branches concerned are responsible for its care and well being. With the mounted branches this offers no difficulty, but the bulk of an army is infantry, and the mules attached to each regiment or brigade are placed under the care of an officer who, probably, has never in his life had anything to do with animals. Under these circumstances the management is necessarily bad or defective. The strain on the first line of Transport is greater than on the others yet to be considered, as it has to keep up with the troops and accompany them in action.

*The Second Line Transport* consists of animals which drag the baggage of the troops and carry two or three days' supplies of food and forage. This transport is not under the management of regiments, but of specially trained transport officers of Army Service Corps Companies. It may consist of both mules and oxen. It follows behind the force, coming up with it towards the end of the day. Unlike the First Line, it does not leave the road or track, nor accompany the troops.

*The Supply Column* consists of mules or oxen, generally the latter, dragging along one or two days' supply of food for the whole Force. It marches behind the Second Line Transport. It is fed by a *Supply Park*, containing three days' rations for men and animals,\* which works to and fro between the rear of the Army and the Advanced Base of Supplies.

The details of the Supplies carried in these various organizations vary according to circumstances, and do not concern us as long as the general principles involved in the employment of transport animals in the Field is understood. For instance, the waggons of the Supply Column are daily getting lighter until refilled; similarly the work of animals with the Supply Park, on their return journey with the empty waggons, is a relief which has to be taken into consideration in judging of the extra marching they perform. The First Line Transport, on the other hand, is always kept at full working strain, and animals showing the effect of this may advantageously be placed under lighter conditions in the Second Line. Mechanical traction will, in the future, revolutionize transport arrangements in the Field, but can scarcely be taken into account during the war in South Africa, where it proved disappointing.

\* "Records of Roughriders," 1907.

† C. of E. Rem., Q. 3813.

\* The number of days varies, depending on the operations. It was seven in the advance from Bloemfontein, but is generally three.

The above is an outline of the organization in South Africa with a large Force; there were modifications to meet the requirements of mobile columns.

It may be mentioned that a team of mules consists of ten animals in a four-wheeled waggon, the load being 3000 lb., and six animals in a two-wheeled vehicle, the load being 1500 lb.

#### MULE TRANSPORT.

The value of the mule as a transport animal, his powers of endurance, his spirit and willingness, have been abundantly testified to in these pages; they won for this splendid animal the admiration of the army. The type of mule we refer to is the small one; the large mule—which, like large horses, we insisted upon importing in the early days of the war,—was not a success; in fact, it may be stated as a general rule that the value of a mule for transport purposes is in inverse ratio to his height. I know of nothing in the way of an animal which, for real "grit," approaches the small mule.

The care of these animals left a great deal to be desired; the creation of an enormous Transport Service necessarily led to the employment of officers with no knowledge of the care and management of animals.\* The few trained officers of Army Service Corps available for Transport Service were almost lost to view, and the management of mules in those Transport Companies where no Army Service Corps officer existed fell largely into the hands of civil conductors. The South African native is an excellent man with mules, but, like all of his class, requires constant supervision. His system of turning mules out to graze was to tie three or four together, and let them roam; the same system was followed when taken to water. It resulted in the strongest having his way, he moved on in grazing, dragging the others from the "bite" they had just found, or when he had finished watering he at once left the stream and the others had to follow. It took months of work to control this iniquitous system, and even at the end of the war it constantly had to be looked for and guarded against. Tying four mules together for grazing is a time-saving process when they have to be driven back to their camp, for the mule is difficult to manage when he has his freedom; but no such consideration should have been permitted to carry weight where the health and vigour of the animals were concerned. Knee-haltering adopted while grazing was a fruitful source of injury, owing to the raw hide used as a rope cutting the limb when carelessly applied. Losses from drowning by watering mules tied together in batches, or knee-haltered, were frequent, and the least reflection should have shown the danger of such a proceeding.† We have no hesita-

tion in saying that the South African method of tying these animals together for grazing and watering purposes, was the chief cause of their rapid deterioration in the early stages of the war in Cape Colony. for a mule thrives on grazing on which a horse will starve.

The daily ration for mules was 5 lb. of mealies, or rather less than three-fourths of what they should have received. The ration should have been not less than 8 lb. daily. As a matter of fact we have repeatedly seen in these pages that they received no rations whatever during some military operations, and frequently only on a considerably curtailed scale. Insufficient food may be taken as the chief cause of mortality among these animals, for, though the question of "condition" arises, as in the case of the horses, it is not so pressing in the matter of the transport animal, with no weight on its back, moving at a steady pace on a track.

The expression "track" is intentionally employed: there are no roads across the veldt. The line followed depends on the season and the nature of the obstruction in front. The most severe part of the road is met with in the dry bed of a river or stream, with its heavy sand-approach and still heavier outlet. The fords have rocky bottoms, but are littered with obstacles in the form of rocks and boulders over which the wheels have to climb. In wet weather, or after rain, the difficulties are enormous. A great deal of suffering might have been averted at drifts and rivers had the principle of extra teams been employed as a regular routine, and not left until the single teams had become exhausted. The passage of a river with almost perpendicular banks means that these have to be prepared for transport, and the newly made track is yielding and heavy. Rivers and streams, wet or dry, were the cause of extraordinary strain on transport animals. In addition, in Natal, hills and mountains had to be climbed. In this respect, the earlier operations in Natal were far heavier than those in the Free State and Transvaal. The difficulties met with on the road have, from time to time, been described in the pages of this history.‡

It is astonishing how well mules maintain their condition, even under adverse circumstances, where they receive reasonable care and attention.† We have elsewhere drawn attention to the absolute importance of the supervising eye of the officer in all matters connected with the care and management of animals. The transport officer's duties are never ending; he is required even more on the line of march than in bivouac. He must see that the pace is properly regulated and animal energy conserved. A steady regular pace throughout, never exceeding four miles an hour with cavalry, and three miles an hour with mixed troops, is fast enough for any military operations. That it

\* At the termination of hostilities there were 40 Companies of Army Service Corps in the Field, with 300 Officers, three-fourths of whom were attached, that is to say, were not transport officers by training, together with 1640 white, and 35,800 native civilians.

† See also foot note p. 25.

• See pp. 32, 33, 75, 76, 86, 92, 95, 96, 100, 101, 102, 103, 105, 153, 155, 157, 170.

‡ In the Evidence taken by the Royal Commission on the War, General Rimington stated (Q. 12,682), he had a team of mules which went through the whole War.

is the pace which kills is an axiom which should ever be before the watchful transport officer. Trotting with loaded waggons is unpardonable. If interval is lost on the road through delays behind, the column in front should halt while it is made good. Up and down his column the Transport Officer should move throughout the march; in no other way can he check irregularities,—such as men riding on the waggons, the abuse of the whip by drivers, the neglect of the brake going down hill, and its removal the moment the point is passed where it is no longer required, the ungreased wheel, so fruitful a source of exhaustion, the chafing of harness,—all these can be seen at a glance, and controlled. To ride at the head of the column looking straight to his front is the last duty of the officer in charge; he might, indeed, be just as well miles away.

The fitness of transport mules depends entirely on the attention to details of this kind; every commander should be as well acquainted with them as the transport officer. In that way, unreasonable calls on the transport would not be made, and the necessary consideration shown for rest, watering and feeding, on the basis of two hours in every four. Those military operations where time cannot be spared to rest and feed the transport are few in number; it is the sacrifice of animals unnecessarily made, by ignorance of requirements, which causes the preventable loss on a campaign.\* Everyone knows that without transport an army is tied to the ground on which it stands. During the War there were several Commanders whose interest in transport was deep and lasting, and their marches have been duly recorded in this History.

There is no animal which returns so much for so little attention as a mule; he has a marvellously economic digestive apparatus which converts the most unpromising looking material into bone and muscle, and it may be laid down as a rule, to which we know no exception, that if mules are in bad condition their management is defective, or unfair calls are being made upon their strength.

The total loss of mules in the war, see p.226, was:—

Oct., 1899 to Dec., 1900	29,113
January to December, 1901	14,433
January to May, 1902	7,853
	51,399

Over 35% of the strength of mules was, as a mean, lost year by year, throughout the war.

The diseases affecting mules do not differ from those attacking horses, and will be considered later.

\* The disgraceful overdriving of animals and overloading of vehicles formed the subject of several Army Orders, they have been reproduced at p.144. Every endeavour was made by the Commander-in-Chief to inculcate humane treatment of animals and attention to their requirements. Even prizes were, as we have seen, offered for competition among native drivers, though they had to be withdrawn subsequently.

#### OX TRANSPORT.

The ox is the transport animal of South Africa, and its management and care are thoroughly understood by Transport Riders and natives generally. The Transport Rider, in the pre-railway days, was a person who undertook the general transport work of the Colonies with cattle and waggons, either his own property, or generally hired. He was, of course, a white man, and his object was to reach his destination with the least possible loss, and by the most direct possible route. Under his skilful management oxen were capable of rendering immense service. As a transport animal, where time is no object and roads are heavy, the ox has no equal. Obedient and willing, endowed with great philosophy, he hauls heavy waggons and immense loads over tracks from one end of a sub-continent to another.

The utilization of the transport of the country in which military operations are occurring is a fundamental principle, and it was known that the ox would be largely employed for all operations in South Africa. There is an immense difference between transport work in peace and that in war, but such differences do not lead to any change in the physiological conditions of the animal; these still remain immutable, and if they are neglected, either from military necessity or ignorance, the penalty is heavy. The difference between the management of the ox and that of the horse is as great as anything can well be, and, with few exceptions, all the military officers at the beginning of the campaign who were responsible for the care and management of this animal were ignorant of the question. Their care naturally fell to the Transport Rider, or Conductor, as he was termed in military organization, and the natives in charge.

No food whatever is carried for oxen; they live on the country, and for this purpose require time for grazing; after grazing they need time for rumination. All experience shows that oxen work badly during the heat of the day, and under peace conditions this time is devoted to grazing and rumination.

The best time for working oxen in draught is the early and latter part of the day, but it is obvious that, under military conditions, such a council of perfection may not be attainable. There is no time so bad for horses and men as in the dark, whereas oxen then do well.

Complete ignorance of the care and management of oxen was responsible for neglect of the most obvious measures for their welfare. For instance, a Commander knows that his animals require rest and time for grazing, and he knows that under military conditions they cannot be turned out to graze at night. Yet these matters appeared to carry very little weight with some, who were satisfied if they covered the allotted distance, apparently forgetting the penalty inflicted upon the oxen. There are periods in every march when a

general halt becomes necessary; there are delays at bad points in the road, drift or river, where waggons can only cross singly and with great delay. Miles of transport may thus be held up. A considerate Commander takes every opportunity for relieving his oxen, which would otherwise stand for hours under the yoke; nor does he deny them grazing if any can be obtained near to the track. In ordinary marches, "inspanning" should be delayed as long as possible, especially where there are miles of waggons, as several hours must elapse before the last sections are able to move off. The earlier sections should be given a start of all other vehicles, owing to the slower pace of oxen, which, under the most favourable conditions, should never be greater than  $2\frac{1}{2}$  miles an hour. In wet weather oxen travel badly, and are liable to become foot-sore. Some consideration must be extended to them under these conditions, or the inevitable will occur.

The various orders which were published by the Commander-in-Chief relative to the care of transport oxen have been quoted on p. 144. No effort was neglected by those in authority to inculcate the principles of humanity in their treatment. It was also pointed out that observance of the rules of marching and grazing should never be departed from excepting under real military necessity, nevertheless the mortality continued, and it became apparent that with oxen, as with horses, less care was taken of them in proportion to the ease with which casualties could be replaced.\*

By attention to the principles of ox management, which are neither numerous nor difficult, and by following the skilled advice of those who all their lives have been mixed up with transport-cattle, a large proportion of the shocking loss of life which occurred in South Africa would have been prevented. It is the staff, as well as the rank and file of the Army, which requires educating in these matters.†

A loaded ox-waggon with a span of 16 oxen, will convey 4,500 lb. of dead weight, on heavy, springless vehicles, over the most unpromising tracks at a steady rate of  $2\frac{1}{2}$  miles an hour—the moment the animals are hustled they become distressed. Four hours inspan should be a maximum at a time, followed by two hours rest and grazing; and eight hours work a day, which, with obstacles and difficulties, will probably amount to fifteen miles, is a fair day's work. Few armies under ordinary conditions are expected to cover more ground than this.

#### THE VETERINARY ARRANGEMENTS FOR TRANSPORT SUPPLY AND LOOT CATTLE.

At the outbreak of war the transport oxen were engaged on the hired basis, the responsibility for maintaining the numbers resting with the contractor. In his agreement were clauses giving

compensation for certain diseases. These clauses in Natal and Cape Colony were not identical. Pleuro-pneumonia was compensated in Natal but not in the Cape. Red-water was compensated in the Cape if a contractor's animals were taken into a red-water district. Very early in the campaign the compensation clauses became a source of financial anxiety, and a veterinary officer was appointed Inspector of Oxen in the Cape (see p. 47), part of whose work was to enquire into these claims and as far as possible check irregularities. Another part of his duties consisted in dealing with outbreaks of diseases; the appointment was made on the representations of Colonel Rayment, Acting P.V.O., whose experience of war was considerable, and who knew the trouble which lay ahead among transport animals, especially cattle.‡ Major Sharp, A.V.D., was subsequently appointed Veterinary Inspector of Transport Oxen, and remained with this Department to the end of the war. The pages of this History give no notion of the amount of good work which this officer carried out.

The system of hired transport is a great convenience for a short campaign, but ruinously expensive when operations are prolonged. In November, 1900, it was decided that the Government should take over from the contractors the whole transport as it stood, and 30,600 oxen were purchased. The unit of organisation of the Ox transport was the Company, and each Company consisted of a variable number of sections, depending on requirements. A section consisted of 10 waggons, each with 16 oxen forming a span. There was a Conductor (civilian) to every section, and a head Conductor to every five sections.

On the Lines of Communication the Headquarters, really Depots, of Transport Companies were located; at these the various sections of transport were held for the efficient working of that portion of the line allotted to it. Spare animals were also kept on charge so that exchanges of weakly animals could be made with convoys and columns. The grazing of the resting animals at these depots and the early removal of debilitated working oxen from columns was an especial duty of the responsible officer at the Headquarters of Transport Companies. The above organisation took some time to establish, and was the outcome of experience as the campaign settled down more and more into that of a Guerilla War. During the large operations such as have been dealt with in 1899-1900 no such systematic arrangements existed, nor were they practicable until the army was in possession of the country.

We have seen at p. 120 that a Transport "Live Stock Recovery Department" was formed on 7th January, 1901. It was charged with the duties of collecting all Government animals strayed or dropped from the line of march, establishing depots for their reception and re-issue to Transport service,

\* See, "Revised Instruction for Transport Organization and Administration," South Africa, Feb., 1902, para. 64.

† See p. 51.

‡ The help and advice given by the Veterinary Department of Cape Colony in this matter, has been acknowledged at p. 47.

and guarding against any cattle being used as slaughter stock which were capable of being utilized by Transport for work. It was impossible to maintain large numbers of debility-animals at the Transport Depots on the Line of Communication, as they ate up all the limited grazing; *Debility Farms* were, therefore, organized. Each of these had a permanent staff calculated on the number of animals present. The veterinary organisation was under Major Sharp, who had a part of the farm told off as a receiving depot, into which all new animals went for 14 days quarantine before being permitted to mix with the other cattle of the farm. These were subsequently branded, classified, and inoculated against pleuro-pneumonia, and later against rinderpest.\* On recovery from this they were turned out with the other stock. The magnitude of this task may be realised from the thousands of debilitated oxen to which this system had to be applied. It was not possible to carry out the work without a technical staff, so Major Sharp selected intelligent men who were trained in cattle diseases and inoculation. They were then treated as Inspectors and received a special rate of pay. These men were entirely under Major Sharp's orders, and travelled about from point to point as required.

*Farms for Supply* purposes were also formed, quite distinct from but possessing the same general principles of organisation as those adopted in the Transport Debility Farm. When the Guerilla War was fully established and extensive clearing operations undertaken, the collection and disposal of loot and dairy stock became an extremely important matter. The loot-stock was drafted either for Transport or Supply, the dairy stock led to the establishment of *Dairy Farms* for the supply of milk to hospitals.† The farms for the above three purposes were located in the Transvaal and Orange Free State only. Twelve farming districts were formed, each under a Chief Superintendent. Each district contained a number of farms, and the total number of these at the close of the war was eighty-six.

The introduction of vast numbers of loot, dairy and mixed stock destroyed the original safeguards created on the debility farms in the way of quarantine; it was no longer possible to carry them out; the numbers were too large to handle, even too large to find grazing for without creating further centres, or, in the case of "supply" cattle, moving them in the direction of the troops where they could be used as food. For the movement of masses of cattle and mixed stock a body of men known as "Cattle Rangers" was organised. They received pay and a bonus for all stock-running successfully carried out for a distance. The men, excepting in a few cases, knew nothing of the work. Rest for the animals, time for grazing and rumination, were either never

contemplated or else neglected. The herds and flocks they attempted to drive were too large for management, the sheep were over-driven and suffocated; thousands died as the result of ignorance. The "Cattle Rangers" disappeared as an organisation, and their place was taken by "Stock Farm Guards" organised under an officer.

The rush of animals with every sweeping movement was not the only disturbing factor: each rush brought disease in with it, and when rinderpest broke out it was evident that it could only be a matter of very short time before all the Government farms became infected. Desperate efforts were made to immunise the animals already at these places, but material did not exist in sufficient quantities, and obviously the working-oxen with the various transport companies had first claim. In course of time all working animals were inoculated, but time and again fresh outbreaks occurred in the spans of working oxen due to the introduction among them of refugee or loot stock which had not been previously protected.

We have seen something of the immense numbers of loot cattle and mixed stock which were brought in by columns, yet in the first instance only a proportion of these found their way into the various farms. Many of the animals were dropped by columns and recovered by the enemy. Sheep were especially difficult to bring in, for they could not keep up with the troops, were unable to cross rivers, and the daily marches were far too long for them. Cattle were lost through being retained by columns and in other ways. As a consequence a Collector of the Military Stock Department accompanied each column, who took over and accounted for the captured animals, oxen, cows, sheep and goats. These suffered from every bovine and ovine scourge, pleuro-pneumonia, red-water, gall-sickness, scabies and rinderpest; among the sheep \* scabies existed to an extent which can hardly be conceived, for towards the end of the war none of the flocks had been "dipped" for two or more years.

In stock of all kinds the winter cold played havoc with animals already starved and overworked; tens of thousands died from this cause. The working oxen were protected by clothing, a condition they were not used to, and one with which we cannot agree in face of the prevalence of skin disease. What they required was fuel within to maintain their body heat, and this was seldom or never obtainable in sufficient quantity. The ox of South Africa knows no other food than grass. We attempted late in the war to make up deficiency in grazing by the administration of mealie meal† and occasionally oil cake, but it was overlooked that the grain-digesting power of these grass-fed animals

\* All oxen inoculated against rinderpest were branded on the near side with a crown brand.

† Agricultural farms were also established for the supply of vegetables and fruit to both the sick and the troops.

\* The condition of these animals was such, that a whole carcase, when dressed, frequently weighed no more than seven pounds!

† The mealie meal was fed off feeding cloths or sacks laid on the ground. This meal being the staple ration of natives, rigid precautions had to be taken to prevent pilfering.

was probably most imperfect, and that under any circumstances a ruminant requires bulk if his digestive apparatus is to work effectively. When no grazing was available during the winter months, a ration of 20 lb. hay was allowed, or 10 lb. if mealie meal (3 lb.) was given, but we have seen, at p. 217, the difficulties in obtaining this supply, even when close to the line of rail.

The number of animals which passed through the loot stock farms varied with the operations in progress. During the last six months of the war, when one would have thought that not a living head of stock remained in the country, there were brought in by the columns a monthly average of 3800 oxen, 10,500 slaughter cattle, and 55,000 sheep.

In the debility farms of the Transport Service the animals died at the rate of 25% to 35% a month.

Among the working oxen of the Transport Companies the monthly death rate before the outbreak of Rinderpest varied between 4% and 8%; during the Rinderpest period it rose to 18% a month. The total number of deaths among transport oxen during the last seventeen months of the war was 125,000, or a mean of over 7300 head of cattle a month.

At p. 143, it is recorded that for the first fifteen months of the war 70,000 oxen had died, been destroyed or captured; for the last seventeen months 125,000 similarly disappeared, or a total of 195,000 for the whole period of the war.

The amount of work done by the Veterinary Service in connection with the Transport Department has never been fully realized for the reason that transport animals excite little interest, and so few really know what is being done for them. The brief account we have given shows the gigantic nature of the task, the marked ability of Major Sharp in conducting the technical side of the cattle work, and the necessity in the future of making some better provision for the care and management of oxen on service.

#### BRANDING.

The indelible marking of all Government animals in the Field is a necessity. In the case of horses the maintenance of army numbers on the feet was obviously impossible; they grew out and could not be replaced. All the horses were directed to be branded on the quarters with a Broad Arrow, and the same order applied to mules and oxen. It has always appeared to us that this practice lent itself to great cruelty, and in the hands of unskilled persons, unused to the application of a red-hot iron to living flesh, it entailed great barbarism and unnecessary suffering (see Fig. 5, Plate iii.). Nor were the brands confined to the Broad Arrow; instructions were issued for the branding of horses on the shoulder with letters indicating their nationality: the object of this was to secure reports on horses at the end of the campaign which should leave no doubt of their country of origin. Later on cattle

were branded with a crown on the side to show they had been inoculated against Rinderpest.

Branding frequently led to sloughing of portions of the skin. It was not realized that any letter which involves an irregular circle, such as a B, isolates a portion of skin which will certainly die if the brand has been severely applied. Every brand should be made with the letters or figures broken as in a stencil plate, even the Broad Arrow, which does not isolate skin, should be broken, for the reason that sloughing will occur at the point where the three lines meet. Brands, of course, may be manipulated by the unscrupulous, but this should not prevent a humane type of instrument being employed.

We are strongly of opinion that with cattle, branding on the horns should have sufficed, and that an animal with a horn cut off should have been regarded as Government property. The distressing scene shown in Plate iii., enacted on tens of thousands of animals, would thereby have been prevented.

The marking of horses and mules in the future need not be more painful than the infliction of a tattooed broad arrow on the inside of the upper lip; for cast animals a line can be put through it.

#### PICKETING.

No method of tying up animals living in the open has yet been devised which is free from objection; the head rope and heel rope are as old as war itself, and both are open to grave objections. Head ropes last but a very short time; it would be interesting to know how many were used up during the campaign, for there were no articles of horse equipment in greater demand. The average head rope is not constructed with any knowledge of the strain and wear to which it is exposed. Only those who have had to deal with a mass of horses, with no means of securing them, can appreciate the helplessness which results from being without head ropes.\* If the head rope is retained it should be of hemp and of such a length that getting around the hollow of the pastern is an impossibility.† A head rope should only be sufficiently long to allow the horse to lift his head to the normal position when standing vertically over the peg or ground line. The horse, for instance, in Fig. 6, Plate i., is correctly tied up, and by no means can a heel-gall from the head rope arise. The next animal to him is badly tied up, *i.e.*, has a long head rope, which, when in the act of turning back to his right position, will in all probability get over the hind heel.

The picket line in all corps which use wheels should be an air and not a ground line, for in this

\* See p. 72.

† The length of a head rope cannot be left to the discretion of the men, as injury is certain to occur from heel-gall. See Plate i, Fig. 5, for the mechanism of production; this is a fore leg, a trifle compared with a gall of the hind heel.

way the risk of heel-galls is entirely prevented. An excellent method of securing cavalry horses is by means of a fore-foot shackle and peg. In this case the head rope is dispensed with. The peg must be of iron, and an iron peg is a clumsy thing to carry on a horse, and if not driven in flush with the ground is a source of serious damage through the animal lying on it. The nature of the soil affects the peg question; in sand it will not hold, in rock it cannot be driven, in ordinary soil it holds well but is difficult to take up, nevertheless, the fore-foot shackle has many advantages.

The method of picketing adopted must be capable of affording security to horses both under ordinary and exceptional conditions. It must be able to stand the strain of panic. Hardly a year passes that a stampede of military horses does not occur, frequently from the most trifling cause, and it happens on service even when horses are tired and underfed. Nothing should lull a commander into a false sense of security,—for the report of a rifle at night, a thunderstorm, or a piece of paper blowing through the lines may be quite sufficient to leave him with no horses in the course of a few minutes.

The true appliance for securing a horse in the open against kicking, stampede, or getting loose at night has yet to be devised. It must be simple, strong, light, free from buckles, readily removed in the dark, with nothing to get out of order through wet and mud, and must not prevent the animal from lying down. It ought not to be impossible to obtain this, and a prize of a thousand pounds would doubtless secure it. No one with a knowledge of injuries occurring on the picket line would consider such a sum as ill spent. The cost of fractures resulting from kicks in a single year during peace would more than pay for it, while the increased efficiency and the reduction of casualties is beyond money value in war. Few people realize what these casualties represent in point of numbers, and that a horse with his hind heel over the head rope, may in a minute or two inflict, in his panic-stricken state, an injury which will take many weeks to heal.

#### DISEASES AND INJURIES.

South Africa is a country of animal diseases, and from the first considerable apprehension was felt in this respect. Nor did it belie its reputation; never again, let us hope, will a veterinary service have such opportunities for seeing contagious and other diseases on a scale which baffles imagination. It is simple to speak of twenty to thirty thousand sick horses a month, but the mind is quite unable to grasp the real significance of these numbers. A horse is allowed three feet of width in the ranks. If, on this basis, the 20,000 sick were formed up in line, they would extend for over eleven miles, and this only represented the wear and tear for one month in South Africa.

In this section it is intended to consider the chief diseases contributing to this inefficiency. It is a regrettable fact that no complete return of sickness for the whole period of the war exists; we are dependant upon fragments—valuable as they are—for an insight into the class of affection which occurred.

The records of 39,400 admissions to Field Hospitals show that every 1000 cases were, in round numbers, built up as follows:—

Debility	-	288
Mange	-	235
Wounds	-	190
Lameness	-	178
Various	-	109
		1000

In this table the proportion of debility appears lower than one would have imagined, but mange and debility were so commonly associated that many cases of debility fall into the skin group.

An important distinction must be drawn between the class of case admitted to hospital and that occurring in the Field. For instance, Horse sickness, Tulp poisoning and other rapid affections would never see hospital, nor, in theory, would cases of clinical glanders or farcy, though thousands found their way there. All the debility cases would not find their way to hospital, only those which had strength enough to leave the Field and to withstand a long journey by train. Others passed direct to Debility Farms under the care of the Remount Department, and in this way many thousands escaped record. Nothing like the number of sore backs occurring would be sent to hospital, the hopeless cases being destroyed on the spot, and the less severe dealt with locally, and so with lameness, fractures, and other injuries. The cases reaching Field Hospitals were those that had passed through the pores of the filter, and it is for this reason that the percentage of cured is relatively high, the mean being 61% among the above 39,400 cases.

On the other hand, we must not lose sight of the fact that had horses and mules been sent to hospital earlier in their trouble better results would have been obtained. In the first part of the campaign they were retained by corps and worked out; matters improved during the latter half of the war owing to orders being issued on the subject (pp. 194, 195), and to the fact that hospital accommodation existed. Defective as this generally was, from circumstances not within Departmental control (pp. 193, 194). There can be no question from a point of utility and humanity that these cases would have been better in hospital than being dragged about the country by corps.

During the year May, 1901, to June, 1902, 11,184 admissions to the veterinary hospital at Middelburg, Transvaal, gave a recovery percentage of 70,\* or

\* I am indebted to Major R. C. Cochrane, A.V.C., for these figures.

some 10% better than the mean of 1901; this represents a saving in one hospital of over 1800 horses. It is unfortunate that the figures generally for the year ending June, 1902, are not available, but there is good reason for thinking that the results obtained in other hospitals during the last year of the war were equally favourable.

In the table (given at p.197) of 24,606 cases—only a fraction of those admitted to hospital during 1901—the death rate was 8.7%, the destructions 26.5%, or a total mortality of 35.2%. The 11,184 admissions to the Middelburg hospital gave a death rate of 4.31%, destructions 21.4%, or a total mortality of 25.71%, a saving of nearly 10% as compared with the mean of 1901.

It is not necessary in this notice that each class of disease should be separately examined, the subject is too vast; the statements must be general, and confined to those diseases which have proved the heaviest source of complete or temporary loss in the campaign. Before taking these up attention must be drawn to a Veterinary Report written by Colonel Matthews, dated 15th July, 1900, when it was believed the war was over. It is published in Parliamentary Paper, Cd. 963, see this History, p. 191. In it he says:—

“There has been notable immunity from contagious and ordinary disease, except glanders . . . . Isolation and mallein test have enabled its spread to be prevented. The numerous—about 500—outbreaks have been quickly suppressed . . . . There has been exceptional freedom from indigenous disease, and in the whole effective of horses and mules (210,000) there have been during the past unhealthy season under 200 deaths from ‘horse-sickness,’ or less than half the deaths that occurred amongst horses [of the civil population] in Pretoria . . . from this disease in the same period.” He adds that the 45,000 mules of the army had “been generally free from disease, and losses by death, except from exhaustion, extremely rare.” “Glanders,” he states, “appeared in numerous instances, but its spread has been prevented.” Finally, the same report deals with oxen, and we are told that the 57,000 “have been generally free from disease.” That pleuro-pneumonia had not been allowed to spread, destruction and inoculation being practised. He refers to cases of “red-water” having appeared, and that precautionary measures were under consideration.

Now this report is an authoritative statement regarding the prevalence of disease among the animals of the army up to the end of June, 1900. It is better than one could have hoped. Skin disease is not mentioned; at this time it had barely begun. Glanders was under control, and good fortune had spared us from horse-sickness during the summer campaign. No reference is made to the existence of Biliary Fever. We are told that the casualties chiefly consisted of Exhaustion and Saddle injuries, and readers of this History will have no difficulty in recognising that the statement subsequently presented to Parliament represented matters as we have seen they existed. There are no tables published with this Report, or the losses from exhaustion and saddle injuries would have proved alarming, but dealing with disease we may say that up to June, 1900, nothing in the way

of epizootic affections had occurred which could not have been dealt with in a short time, had peace followed the capture of Pretoria. The whole of the serious trouble from disease took place during the two subsequent years of the campaign, the seeds, of course, having been laid during the first nine months of the war.

The pages of this History have largely been devoted to a consideration of the organisation which existed for dealing with the sick. There was no organisation worthy of the name, no hospitals officially existed, the sick had to trust to good fortune; in fact, it would almost appear that no sick were expected in spite of the fact of the notoriously unhealthy nature of the country for horses.

We do not intend here to survey the painful history in this respect caused by official neglect, but it is well to indicate where, in these pages, the development of a system for dealing with sick animals in the Field is recorded.

[The letters after the figures indicate the position on the page where the information will be found. The pages are divided into four roughly equal parts, a, b, c, d; the letters follow the text, thus a and b are in the left column, c and d in the right].

#### HORSE-SICKNESS.

It is convenient to take this affection first; it was the one of all others which caused natural apprehension to the authorities from the beginning of the campaign. Precautions against the disease had already been drawn up in November, 1899, at the suggestion of the Civil Veterinary Department in Cape Town, prior to the arrival of Lieut.-Colonel Rayment. These instructions contained the cream of colonial experience of this malady, supplemented by the reliable knowledge of Dr. Hutcheon and his officers. There is no necessity to reproduce these instructions which were precautionary measures, and not always practicable under military conditions. We have seen that fortunately the first horse-sickness season was mild, and did not trouble us seriously, but during the two subsequent years 5700 fatal cases among horses, and 2000 fatal cases among mules, represent a part of the toll paid for operations in deadly areas. It cannot be supposed that anything like the full number of cases was ever recorded: on the other hand, many must have been reported as fatal horse-sickness which succumbed to other trouble. The large majority of the above fatal cases occurred in the sickly season 1900-1901\* (the disease lasts from November to May), the succeeding year proving healthier.

We learned nothing about the disease during the war; active operations are not conducive to clinical or pathological studies. Every Colonial has a remedy which, of course, is infallible. The Authorities were pestered by these people to give them an opportunity of treating the cases with their specific. Several of these persons had never seen the disease, but had heard of someone who did so-and-so, and never had any more trouble! The following is an example of the kind: A gentleman in the Cape Peninsula—where the disease is practically never seen—informed the Authorities that a certain Reverend gentleman had been advised by General Joubert that a small piece of assafetida, weighing about 50 grains, should be tied to the bit and renewed every eight days. General Joubert had followed this practice, it was said, and had never lost an animal, but the quantity must not exceed 50 grains, nor be used oftener or less frequently than once in every eight days.

Another method of treatment was distinctly heroic, and consisted of the administration of six grains of strychnia, which acted as an antidote provided the horse had the disease, but otherwise, as the prescriber acknowledged, killed it.

These may be taken as fair samples of the volume of advice offered by interested and disinterested persons. In practice, we relied on preventing early morning and late evening grazing. The use of

nosebags containing disinfectants, of which creosote was largely employed, appeared to be worthless, and rendered the bag unfit for the purpose for which it is intended. The avoidance of low lying ground as bivouacs and camps is obviously not always a practicable condition on service, valuable as it is as a preventive. The administration of arsenic as a prophylactic was highly spoken of by many with experience, and in the case of a patrol into a dangerous belt might be employed, but the wholesale use of arsenic in the Field (see p. 48 of this History) would have led to some deplorable accidents, and further, is not practicable.

#### GLANDERS.

The British Army at Home had been free from glanders for several years before the war, but those who knew something of campaigning were fully aware that this condition of affairs on service could not last long, and that the disease was bound to find its way in through new purchases and other sources. Far less anxiety was felt, however, in connection with this question, as a new agent for diagnosis had recently been discovered which enormously simplified matters, though on the other hand, it had to be remembered that the Officers of the Veterinary Service had had no experience of its employment, owing to the fact that glanders did not exist in the army. Many had never seen a mallein reaction, and, in fact, outside large cities the same remark applied at that time to the practitioner in civil life.

It will be remembered that in order to place the army on a war footing, considerable additions to its strength of animals was necessary. The Reservists, as they may be called to distinguish them from Remounts, came out of large studs in cities, and in spite of the care and veterinary supervision these animals received, the chances of infection from glanders was always present. As it happened this class furnished the first cases of the disease carried by troops to South Africa. The s.s. "Rapidan," whose history we have seen, arrived at Cape Town on 5th December, and reported some cases of glanders among her horses (see p. 13 of this History), and the Reservists in these all came from public stables. We do not know the number of cases of this disease carried to South Africa by Reserve horses, but it was probably small.

The animals required to replace wear and tear among the troops in the field, and those necessary for the transport of the army, furnished the large group of Remounts, and among these cases of glanders were numerous. The number thus introduced into South Africa cannot be exactly stated, but that it was considerable may be judged from the following list which contains the names of only a few remount vessels on which glanders occurred at sea, or among the animals on landing:—

\* During this year no less than 1873 fatal cases alone occurred in the Natal District.

		Horses	Mules	From
1900	s.s. "Alsatia"	—	14	Gibraltar
"	" "Australia"	—	40	"
"	" "Cuban"	—	20	New Orleans
"	" "Montenegro"	—	64	"

"	" "Montreal"	35	—	New Orleans
"	" "Wingfield"	—	3	"
"	" "Langton Grange"	4	—	" ? "

This list is not carried beyond February, 1901, by which time the outcry regarding the importation of glanders had been so great that increased vigilance at the ports of embarkation was urged. The result of this additional care was soon evident; nevertheless, 35 cases of the disease were received from overseas (exclusive of cases occurring at sea), in one large coast-depot in Cape Colony, between Sept., 1901, and July, 1902, a vast improvement on the previous condition, but still far short of what was necessary. The above facts enable us to understand how it was that horses of the Regular Forces, free from glanders for several years, were infected in the Field as early as April, 1900. (See p. 60).

The third source of infection was that occurring in the country. Glanders was known to exist throughout South Africa prior to the war. Rhodesia, very early in its history, had made up its mind to rid this young country of the pest while still within reasonable limits, and through the initiative of the P.V.O. of the Rhodesian Government, Mr. Sinclair, this was effected before the war. He saw the whole of his work thrown away through subsequent infection by the troops constituting the Rhodesian Field Force (p. 107). Natal also, before the war had, under the organization of Mr. Watkins-Pitchford, secured legal machinery for dealing with the disease; but in this colony it was more deeply and widely spread, and, as this History shows (p. 24), declared itself very early in the campaign, when local troops were raised and horses obtained from all parts of the colony. In Cape Colony there was probably not a single district which could be said to be free from the disease; legislative machinery, owing to Dutch apathy and ignorance, was not only more difficult of adoption, but met with opposition. The struggle of the veterinary as against the farmer element was constant, and would have been even more acute but for the extraordinary personality of the P.V.O., Dr. Hutcheon.

In the Free State and Transvaal the disease, so far as one can judge, was as widely spread as in the Cape. In the Transvaal legislative machinery existed, but the trained staff to employ it did not. In large centres, like Johannesburg, the disease exceeded anything which could be found in other parts of South Africa. The Republican Forces were not free from the disease when they took the Field. Glanders existed in probably all their large

camps, even at the early part of the war (see p. 38); later on, when forced to evacuate their positions, they very rightly left these cases behind for annexation by the enemy.

In spite of local sources of infection it is clear that the main channel from which the army was poisoned in the first instance was from its own remount supply. The troops were operating away from towns, and in a sparsely populated country. On the other hand, the infection of the locally raised forces was obviously due to infection pre-existing in the country, for these troops obtained no overseas remounts, or at any rate, none at the time when glanders was first found in their ranks. March and April, 1900, may be looked upon as the beginning of the trouble in the Regular Forces; at that time the Cavalry Division was infected at Bloemfontein, the Cavalry Brigade at Ladysmith, and the Remount Depot at Mooi River, in Natal. Those who knew anything of these matters were aware that from these available sources the disease must surely spread to other branches of the service, but it was hoped that a life in the open, in a dry atmosphere and with plenty of sunlight, would retard its development, and such was undoubtedly the case.

By July, 1900, the P.V.O. of the Army was able to report that though up to that date about 500 outbreaks of the disease had occurred, these had been quickly suppressed.\* The number of outbreaks is astonishing, bearing in mind the short interval between March and July, and may be explained by the constant influx of material with both overseas and local remounts.

The next point to consider is by what means the disease spread during the war.

The arrival of ship after ship with cases of the disease was a source of grave anxiety; every Remount Depot was soon infected, either from this source or the serious blunder of admitting into Remount Depots war-worn animals from the front. The latter system, we have seen,† was carried out in the face of Veterinary advice from the earliest days of the war, and sealed the fate of Remount Depots.

The introduction of debility farms should, in theory, have prevented this mixing, but unfortunately debility farms and remount depots were at times side by side, or even combined, and this led to the disasters recorded in 1901 (see p. 202).

There were difficulties attached to these matters which can only be understood by those whose imagination enables them to picture the thousands of horses temporarily unfit from debility and exhaustion, for the care of which no provision had been made other than that of a remount depot. The principle was wrong, and this was pointed out before a shot had been fired. All familiar with horse-management did not doubt that tired and debilitated horses would exist after hard work, but no one imagined the numbers would be on the gigantic scale revealed in March and April, 1900, nor would

\* Cd. 963, p. 14.

† See pp. 23a, 84c, 115b, 116a, 125c, 138c, and 202d.

they have been, had the horses been properly fed. The principle of returning war-worn horses to a remount depot to recuperate was radically wrong, and until these places were hopelessly congested no other system was devised. When later the necessary steps were taken to cope with these ever-growing masses of war-worn horses, the remount depots and debility farms could not be regarded in in any other light than a breeding ground for glanders.

The utilization of captured animals before they had undergone veterinary inspection was a prolific source of infection among all animals, for it included not only glanders and mange, but pleuropneumonia. Carelessness in this respect lasted throughout the whole campaign. The animals requisitioned in the large towns of the Transvaal were also grave sources of infection. In future campaigns rigid instructions should be issued regarding horses captured or requisitioned from the enemy, and on no account should they be allowed to mix with the animals of the Force until found free from disease.

The spread of glanders in the Field by ordinary contact cannot be overlooked, though it was probably less than one might reasonably suppose, owing to the nature of the climate (see ante) and the use of nosebags. There is good reason to think that the frequent infection among mules was assisted by the canvas feeding troughs common to each span, though, as we shall note later, these contrivances have their important dietetic advantages. Infection by means of the water supply cannot be disregarded where troughs were used in standing camps, but was less likely to be operative among animals in the fighting line.

The diagnosis of ordinary clinical glanders in the horse gave rise to no difficulties, but it was otherwise with the acute form, both in the horse and especially in the mule. The mule, like the ass, frequently suffers from acute glanders, sudden in onset, with swelling of the Schneiderian membrane, confluent ulceration, stertorous respiration, so noisy, indeed, that the existence of such cases can be detected in the dark.\* Many were subjected to tracheotomy under the mistaken impression that the disease was local. Such cases may not react to mallein, nor is glandular sub-maxillary enlargement necessary. The ulceration seen in chronic glanders is absent, and the pituitary membrane reveals destruction of such an extensive nature that it is no wonder those who saw it for the first time paused in amazement, and wondered what they had to deal with. The acute form in the horse

was not quite so violent in character, but misleading to the inexperienced.

From outside sources, but mainly through the agency of the Remount Department, it became noised abroad that the veterinary service had blundered, and mistaken glanders for a curable disease known to the Dutch as "new sickness." At p. 203 we have seen how gladly the Remount Department accepted the view of the Dutch, and how skilfully they utilized a difference of professional opinion as supporting the existence of some "new disease." It is not intended to convey the impression that all the cases of "new sickness" were acute glanders, but the Dutch farmer is not a pathologist, and anything he had not previously seen in the horse came under the head of "new sickness"; the cases of acute glanders were thus designated. The opinion held by the Remount Service is quoted at length at p. 203 of this History. This Department did not believe us when we told them their depots were full of glanders; they did not believe us when the dangers of their immense debility farms were pointed out, into which streams of war worn and diseased horses were daily poured. It fitted in with their system of farm management to comfort themselves in the belief that if glanders existed "more would be heard of it," and more would have been heard of it had these animals ever been inspected. We need not again travel over this point; the hideous story is related at p. 202, but we cannot dismiss it without a final comment on the evidence given by the Remount witnesses before the C. of E. Rem: and recorded at p. 203. In this we have seen a layman tendering evidence on a highly specialized and difficult subject, criticising the supposed ignorance of the veterinary authorities, and doing his best to induce the Court to believe that in the matter of glanders we had blundered badly. It so happened that before the same Court a veterinary officer was examined; strange to say he was the officer who had condemned as glandered the particular animals referred to by the remount witness, but it is almost unbelievable that he was not asked a question on the subject of glanders, "new sickness," or supposed mistaken diagnosis. The evidence of the layman on veterinary ineptitude stands uncontradicted, and was presented to Parliament!

The number of cases of glanders occurring during the war can never be known. We have seen (p. 276b) that by July, 1900, 500 outbreaks of the disease had been reported, but the P.V.O. does not give the total number of animals attacked, so that the information is robbed of its chief value. Between April and December, 1900, 2000 animals were destroyed for the disease, either clinical or reactors. From January to December, 1901, 12,000 animals were destroyed for glanders, and of these no less than 9000 occurred in the Remount Depots and Debility Farms of Cape Colony (see p. 204). For the first two months of 1902, the losses from glanders amounted to 1300, and beyond that period no evidence is available. According to these figures

\* In the *Journal of Comparative Pathology and Therapeutics*, Vol. xv., 1902, p. 31, Lieut. (now Major) Cochrane, A.V.D., published a most interesting record on "Glanders in South Africa." He mentions the fact that animals presenting no sign of the disease, after thorough examination, might have within three days extensive nasal ulceration and snoring respiration.

This officer, working in a hospital during active operations, cultivated the bacillus, and employed it to ascertain the protective power of mallein against glanders infection.

during twenty-three out of the thirty-two months the war lasted, 15,300 cases of glanders occurred, and this by no means represents the amount of disease existing, for, as will be explained presently, mallein testing during 1901, was mainly restricted to hospitals, depots and farms.

The above figures are sufficient to show that on the termination of hostilities the army was riddled with glanders; there was hardly a unit in which the disease was not present, the occult cases were daily developing into the clinical variety, and from these further infection was constantly occurring.

In connection with the above we have hitherto made no mention of mallein. It is now necessary that our attitude towards this clinical test should be made clear, and, above all, the vastly important lessons derived from its employment with an army in the Field.

When operations began, the scheme which naturally suggested itself for the control of glanders was that employed in civil life, *i.e.*, destruction of the affected and inoculation of those in contact. This was followed out so far as military movements permitted for the first eight months of the war, but by August, 1900, it was evident that not only had we failed to make any impression on the disease, but that owing to the vast increase of susceptible material, and the constant importation of fresh cases, the disease was rapidly gaining ground. An examination of our position regarding the use of mallein then became imperative, and the following conclusions were arrived at.

The employment of mallein during active operations is contra-indicated, as it leads to the destruction of animals in the early stages of infection, which are capable of weeks, or even months of work: long before the disease can develop into the open stage the majority of these animals, at the then rate of loss, will be dead from other causes. As occult glanders is not infectious no risk is run by allowing these animals to live, and the State to obtain some small return for their cost. In substitution for the mallein test increased vigilance was directed to be adopted in regard to inspection. An examination of the nasal chambers by means of a mirror\* was to be relied upon as the chief source of controlling infection, and no animal was to be destroyed on the basis of the mallein test if in good condition and free from clinical symptoms. This momentous decision, a reversal of the theoretically true policy, was never regretted; inspection took the place of mallein, and the wholesale operations of the latter and destruction of reactors ceased.

The above regulation did not, however, apply to hospitals and remount depots, which were left unfettered in their action, as in these places it was desirable to keep the disease as far as possible under control, but the general principles were

nevertheless not lost sight of. It is obvious a hospital could never be kept free from the disease while cases continued to pour into it from without.

We have endeavoured to make our attitude perfectly clear on the question of the employment of mallein during active operations, and to give a precise statement of the policy adopted.

The action of mallein in cases of acute glanders both in the horse and mule, is not so regular as in chronic glanders, for with the acute variety the animal may fail to react,\* in single, double, or triple doses. The rule is that they do react, but exceptions, especially in the mule, are numerous. As the mule is more liable to acute glanders than the horse, it was discovered during the early weeks of the war that reactions to mallein in this animal were nothing like so certain as in the horse. In order to overcome this difficulty double doses for mules were employed. This system obtained throughout the war and, in practice, was found satisfactory, though its explanation must be left to the pathological laboratory.

Not only do cases of acute glanders in both animals react to mallein with less certainty than chronic glanders, but the lungs in both animals may be free from discoverable nodules on macroscopic examination. We suppose that in such cases microscopical examination would reveal the trouble, but it is beyond all doubt that acute glanders may be present in both animals with extensive destruction of the pituitary membrane, without any nodules being detected in the lungs by the sense of touch.† This fact we assume to be the explanation of the differences of opinion held by one or two veterinary surgeons regarding acute glanders and so called "new sickness."

Both horse and mule which may have failed to react to mallein may develop clinical symptoms later.‡

A glandered mule frequently, a glandered horse rarely, may show no sign of local reaction to mallein at the proper period, yet a marked reaction may be present at the 48th hour. In one case in a horse, of which we have a photograph, a nine inch painful swelling appeared at the 48th hour, and the existence of the disease was demonstrated at the autopsy.

The increased dose employed for the mule appears to be responsible for a complication frequently observed in this animal, for swellings very misleading in character may be produced in a healthy mule at the seat of inoculation. This very important statement is based on a large number of observations; some made after the war may be quoted, as the actual figures are available. Out of 1000 presumably healthy mules, 460 were selected to proceed to Somaliland; from such a wide choice none but

\* The want of adaptability of some veterinary officers when this order was issued was very marked. Mirrors in large numbers could not be issued at once. They forgot their own hand-glass was available, and that any reflecting surface, metal or glass, was better than none.

\* Cochrane, *op cit*, notes the same fact.

† Cochrane records the same important point.

‡ Cochrane relates the case of a horse refractory to three mallein testings, in which complete ulceration of the septum existed.

the best were selected. They were then malleined; double doses being employed. Five animals gave what was regarded as a decided reaction, and in 19 others the local manifestation was sufficiently large to necessitate re-inoculation. This was done with a triple dose, and of the nineteen, three were selected as being glandered. Out of this batch of 460 mules, eight were, therefore, deemed on the mallein test to be affected with the disease, and were destroyed. In only four were lesions found, though, of course, it is possible there were microscopic nodules accounting for the reaction in the other four, but the chief point at present lies in the undue proportion of animals presenting local swellings, and yet free from disease. For instance, again quoting from carefully recorded observations, a mule may have a local reaction 11 inches by 5 inches at the 18th hour or later; this may or may not be painful—though never acutely so—lymphatic vessels may or may not run over its surface; the swelling may be tense or baggy and dropsical, and the animal on P.M.E. found free from the disease.

The following sizes of local reaction are taken from among many, but serve to illustrate this extremely important point:  $7\frac{1}{2}$  in. by  $2\frac{1}{2}$  in., 8 in. by 4 in., 10 in. by  $5\frac{1}{2}$  in., 11 in. by 5 in. In all these cases the animals were destroyed and found free from disease on ordinary macroscopical examination. They were destroyed mainly in consequence of the size of the reactions. All the above and similar reactions measured more in one diameter than in the other, they were longer than they were broad; they were frequently dropsical, and jelly-like. If tense and painful, this was probably due to the presence of enlarged lymphatic vessels. In other words, the local manifestation did not present the true reaction of a glanders swelling, which measures much the same in both diameters, and is painful to an acute degree.

This brings us back to the question of dose. Were the double and triple doses in any way responsible for the size of the swellings? We think that they were. It was found experimentally on glandered animals that if a single dose produced a 4 inch reaction, a double dose might give a  $5\frac{1}{2}$  inch, and a triple dose one of 7 inches in diameter. These figures are only roughly comparative though taken from actual observation, but are useful as indicating in the mule that the extent of the local reaction in undoubtedly affected animals did appear to bear some proportion to the amount of material injected. That the ratio is variable is undoubted, for we have seen a single dose produce a  $4\frac{1}{2}$  inch swelling, and a double dose in the same animal a 9 inch reaction.

It must be remembered in connection with the whole of the malleining done in South Africa, both during and after the war, that the operations were conducted in the open, the animals were exposed to the sun, dust, and sources of local infection at the seat of inoculation; but so were the horses, and with these such irregularities were not common. Aseptic inoculation was impracticable, though at-

tempted, especially after the campaign closed, and sepsis might have accounted for these peculiarities in the mule reactions, though, again, the horses were under the same conditions. This view was ever present in the mind of the attentive observer, and we admit that the large pear-shaped dropsical swellings observed in the mule, especially if associated with local lymphatic irritation, were by ourselves attributed to this cause. Why they should have been so relatively common in the mule we, unfortunately, do not know, but that they led to errors in diagnosis is undoubted.\*

At the beginning of the war the employment of mallein was new to the whole veterinary staff; but the rate at which glanders increased, and the large employment of mallein during the earlier months of the war, soon rendered the majority very familiar with its use,† though the mule ever remained a difficulty.

It cannot, therefore, be said that mallein gives as uniformly good results as a diagnostic agent in the mule as with the horse, or with acute as with chronic glanders. There are many pitfalls for the unwary, and infinite judgment is required in dealing with the puzzling percentage of cases which exhibit reactions which are not truly typical.

Lest, however, it should be felt that these remarks are calculated to raise doubts as to mallein being capable of detecting the existence of glanders in the mule, it may be stated that in 109 animals condemned on the strength of the test, the presence of the disease was verified on post mortem examination.‡ These mules, however, needed larger doses and more frequent re-testing than would a similar number of horses. Where mallein may utterly fail, to give a reaction is in acute glanders, and this applies, as previously mentioned, to both mule and horse.

So little is known of the mule in this country that it is thought these notes on mallein testing may be useful in a future campaign, though, obviously, they leave undecided some important features which we feel assured can only be elucidated by the laboratory expert.

A brief statement has been made at p. 279d, of the number of cases of glanders known to have existed during certain broken periods of the campaign. These only tell us that infection was widely spread, but the percentage of animals affected may be got at with sufficient accuracy through the returns of those malleined. Between April and December, 1900, 24,400 horses and mules were tested with mallein, and the general reaction amounted to 8.6%.

\* It would appear to be desirable to determine whether mallein cultivated from glanders of the mule would be as "irritating" to this animal as mallein prepared from the horse.

† Exceptions are indicated at p. 204c.

‡ We were indebted to Lieut. (now Major) England, A.V.D., for the heavy additional labour this research entailed. It was carried out at the Station Veterinary Hospital, Kroonstad, during one of the most active phases of hostility, and lasted three months.

The majority of the tested animals (15,900) were remounts; 6000 belonged to the Rhodesian Field Force (see p. 107c), and the balance of 2500 represented hospitals and units in the Field. The reaction percentage of these groups can be given:—

Rhodesian Field Force	2.45 %
Remounts	5.3
Units in the Field	7.7
Veterinary Hospitals	15.7

During the next year, January to December, 1901, 28,500 horses and mules were tested; the average percentage of infection was 16, or double that of the previous year, and grouping the units we shall learn where the increase in infection lay.

From	Reacted
Ships and Remount Depots	5.2 %
Units in the Field	6.7
Animals in Hospital *	19.0
Remount Debility Farms	55.0

The table tells us that the two chief depositories of the disease were Remount Debility Farms and Veterinary Hospitals. The infection of the latter is legitimate, they are intended for the reception of sick; but Debility Farms were for the purpose of resting and recuperating war-worn but otherwise healthy animals. The above figures for Debility Farms are known to be incomplete, but they give some notion of the degree of infection. During the period under review, every second animal on the Debility Farms of Cape Colony was affected with glanders in either a clinical or an occult form!

The actual percentage of cases of the disease in Remount Depots and on ships remained at the same point that it occupied during the previous year. It ought to have been lower, for there was much more care taken in the inspection of over-sea remounts, and it is probable that it was lower, and that some of the returns of debility horses were mixed up with those of remount animals. The troops in the Field showed a slight reduction in the degree of infection, but this was due to the better practice of sending the sick and exhausted earlier into hospital. As a consequence the hospital rate was higher in 1901 than in 1900.

It is unfortunate that in the above figures of general infection we are unable to differentiate between horses and mules.

The termination of the war found 161,400 horses, and 93,900 mules and donkeys on the strength of the Army in South Africa,† and the first steps to reduce expenses were directed to getting rid of all surplus animals. How they were disposed of will be mentioned in the section on "Demobilization," but we can anticipate the story by saying part went

to a department known as the "Repatriation," charged with the duty of restoring and restocking the devastated provinces, part by sale to private individuals, and the balance was retained by the Army of Occupation.

Peace came suddenly, and the stock of mallein in hand was quite insufficient to test more than a small proportion of the animals to be disposed of. It so happened that if famine was to be averted the agricultural operations could not be started too early, nevertheless, the Repatriation Department was aware how deeply the army animals were infected with disease, and they hesitated to spend their funds on glandered animals. \* Forty thousand doses of mallein were at once cabled for to England, and in addition, an order for 10,000 doses a month until further notice; but mallein takes time to prepare, and, meanwhile, the Repatriation Department was clamouring for mules and horses, but especially mules. The question of price for these animals created a difficulty between the civil and military departments, which caused a delay favourable to mallein operation, but the stock of 10,000 doses in the country was a mere drop in the ocean, especially with double doses for the mules, and finally large numbers of animals had to be taken over without being tested. These were drafted all over the country and carried glanders with them. Whole teams disappeared, and a bitter cry from the Repatriation Department resulted. Heavy sales to private individuals in the Cape were also effected, the animals being inspected as far as possible, and every care taken to avoid clinically glandered animals being sold, but complaints from purchasers soon poured in. An infinity of trouble and endless correspondence occurred with the various Civil Governments, who naturally viewed with alarm the wholesale distribution of war-worn and possibly diseased horses. Their anxiety was reasonable, for to them fell the work of clearing up the trouble; they pleaded in vain for the mallein test to be applied to all animals sold. The mallein, as we have seen, did not exist; even had it been on hand the skilled staff for applying the test was wholly insufficient for the number of horses to be dealt with in a reasonable time, and so the animals were sold without being tested.

Looking back on the whole transaction it is difficult to know, under the pressure of reducing expenses and the urgency with which the animals were required by the Repatriation Department, what other course could have been pursued. It was bad, but it was the choice of two evils—famine in the Free State and Transvaal or glanders among the agricultural stock. Over 100,000 horses and 31,000 mules were sold without being tested, or rather to no greater extent than some 25,000 doses of mallein placed, at one time or other, at the disposal of the Repatriation Department admitted of. By about September mallein began to arrive in large quantities from home, and animals still await-

\* In one area of the war Cochrane found that out of 12,540 admissions to Hospital between March, 1901, and May, 1902, 2.5% of the animals were affected with occult glanders.

† See p. 229a for the discrepancies which exist in the enumeration of the total number of animals on 31st May, 1902. The Remount Department placed it at approximately 142,149 horses, 76,839 mules, 12,864 donkeys.

\* See p. 229a.

ing disposal were dealt with, but the bulk of the sales were over, and the damage done.

There still remained for testing the horses and mules of the Army of Occupation. This had been provisionally fixed at 20,000 horses and 25,000 mules, and by October the work was systematically taken in hand. At this time the amount of glanders should have shown signs of shrinkage, for inspection had been constant for months, with the object of eliminating all clinical cases, yet some 3000 mules, tested for the Repatriation in the month of October gave, as the result of the mallein test, 26% of reactors, while 28% of clinical cases were picked out. Whatever doubt may be cast on the accuracy of the figures dealing with reactors there can be none so far as the clinical cases are concerned, which revealed a degree of infection almost beyond belief. The mules had been huddled together for months awaiting disposal, and under these circumstances infection was readily ensured; they belonged to the Repatriation, who refused to take them over until tested. Their care was repudiated by both sides, with the result that barely a half survived.

The amount of disease among the horses and mules of the army awaiting testing was naturally much less than this; they were under proper supervision and inspection, and clinical cases were eliminated as fast as they occurred. When mallein operations took place the following results were obtained:—

3000 horses gave	7% reactors
5000 mules „	5% „

These numbers are probably large enough to establish the proportion of latent cases existing in the Army of Occupation before the final clearing up of the disease was begun. It is unfortunate that the figures for the entire operations are not known.

The task now in hand was a gigantic one—20,000 horses and 25,000 mules had to be tested, and the reactors eliminated; body temperatures were not available as the animals were all in the open, and the season summer.

The principle adopted in Cape Colony was as follows:—Each unit was separately taken; it was enjoined that no hurried measures were to be adopted, and two experts in malleining,\* in addition to the officers in veterinary charge, were to be employed. For a month previously nothing was to be done but systematic inspection; double the ordinary interval was to be given on the picket line, each horse or mule was to maintain its position on the line, and every animal was to have its own nosebag clearly marked with its number. No inspection of the nasal chambers was accepted that had not been carried out with a mirror, and 150 horses a day was considered the effective limit for mirror inspection. The watering arrangements were rigidly supervised; if from a trough, no suspect was permitted to be watered excepting by means of a bucket which

bore its number. If a stream was the source of water supply suspects were watered last. At the end of a month malleining was to be carried out, not more than 100 horses being submitted to the test at one time. The results of this were to be grouped as follows:—healthy, suspicious, gravely suspicious. The two last groups were to be isolated and on no account mixed; the suspicious and gravely suspicious groups were to be at once re-malleined.

Instructions were issued regarding the disinfection of the site of inoculation and of the needles between each operation.

The results were to be interpreted by the local reaction and character of the swelling, 3½ inches in diameter being regarded with suspicion. In all cases of doubt the animal was to be given the benefit, and a fresh inoculation made on the opposite side. Animals were not to be condemned until the 24th hour, and in case delayed reactions appeared the group was not to be dispersed for three days.

By March, 1903, nearly a year after the war, the disease was well in hand, but in spite of the precautions taken the chances of infection were so numerous, due to the widely spread character of the disease, that it was impossible to eliminate all cases at once. Between April, 1903, and March, 1904, 114 horses and 51 mules were attacked, mainly amongst the cavalry regiments and remount depots, but the disease was so well in hand that its obliteration was within sight. In the following year, *i.e.*, March, 1904, to April, 1905, 31 cases occurred, mainly in remount depots, and the disease then died out. It was thus three years from the date of peace before a clean bill of health could be given, not, perhaps, a long time considering the wide-spread nature of the disease and the fact that glanders was only one of four plagues being fought at the same time, for the army was full of mange, epizootic lymphangitis and specific ophthalmia.

The persistence with which the disease clung to remount depots can readily be understood, for in these places stabling existed. What was too good to destroy was dealt with by burning the walls, scorching the wood-work, and replacing the earth floors after previous burning. The wood-work was then given a coat of creosote, but such work as this requires constant skilled supervision to ensure thoroughness, and with the extraordinary pressure of work and a small veterinary establishment it was not possible to detail special officers for this duty.

A few words are necessary regarding the source of mallein supply. During the first half of the war mallein was obtained from the Royal Veterinary College, London, and from Colonial and Foreign sources. The two latter were as a rule unsatisfactory, and certainly contained some irritating substance; so violent were the reactions in the case of the foreign mallein that an investigation was made as to it possibly having been tampered with, but nothing resulted. No officer wished for any-

\* Captain (now Major) Wilson, A.V.D. and C.V.S. (now Captain) Jelbart, were the officers selected for this duty.

thing but the London College mallein, and for the remainder of the war this was entirely depended upon.

The amount of mallein sent to South Africa during the war is not uninteresting.

From	Doses
Oct., 1899, to Dec., 1900	101,500

One final point may be referred to: it seems incredible, with such wide-spread infection as the figures for 1900-02 represent, that the whole force was not destroyed, including many of the men. For this the climate is responsible, sunlight and dryness sterilized where moisture would have maintained vitality; discharges which would have retained their virulence in Europe were rapidly killed by desiccation, and this, no doubt, was a helpful factor in the campaign which was subsequently undertaken against the disease.

The occasional death of men from glanders, in the Field, might readily escape detection, that is if we may judge by the fact that in a city like London there is evidence to show that it was not infrequently overlooked. Nevertheless, considering the number of men engaged and the enormous extent to which glanders existed, it seems impossible to believe that had the disease occurred amongst them it would have remained indefinitely unidentified. The risk of infection one must believe to have been considerable. Sores on the hand, scratches and injuries, blistering of the face from the sun, the absence of cleanliness, are conditions for infection which it would seem impossible to improve upon, yet we believe no case of the disease was reported among the troops nor among the natives of the transport.

#### MANGE.

The number of cases of mange occurring in the army among horses and mules exceeded that of any other disease, there were tens of thousands of cases. We have seen, at pp. 13 and 19, that we took sarcoptic mange to South Africa with the 6th Dragoons, but this, of course, was not the only nucleus of infection, for we imported it with remount animals and also contracted it in the country from affected horses left behind by the enemy.

Mange, however, gave no real cause for anxiety for the first few months, though it was known not only at Naauwpoort in 1899, but at Modder River in December, and Sterkstroom in the following February, the latter cases being derived from Remounts issued at Queenstown. It was not until June, 1900, that the matter was seriously heard of (see p. 83b), and this is borne out by the report of the P.V.O., written during that month (see p. 276b), in which no mention of the disease is made. By the following September matters were so serious that a

circular was issued notifying the prevalence of mange in the army. This instruction directed the frequent inspection of units, the non-transfer of doubtful cases to other regiments, the segregation and treatment of the affected, and the destruction of those obviously useless. The disease had secured a hold which it was evident would not be relaxed during the operations, and later on, it is safe to say, that hardly a single unit was free from the affection; it was rampant in remount depots and debility farms; it affected horses, mules and oxen. It could not be excluded from debility farms, but Remount Depots were infected by taking in horses from the front (see p. 138c), and by the acceptance of cases from overseas.\*

In the first instance it was difficult to cause those in authority to take a serious view of matters. This may to an extent be explained by the fact that skin disease among horses in South Africa was not regarded by the inhabitants with apprehension, for colonial horses in that country are liable to an affection attacking the back, loins and withers, which, in its clinical features resembles mange, and yet such cases are spontaneously curable when the winter coat changes. The Burgher, from observation, knew it was not contagious. We have no doubt whatever that these facts explained why the representations of the veterinary service were not taken seriously. On 10th August, 1901, a year after mange was known to be widely spread throughout the Force, the Inspector of Remounts, South Africa, wrote as follows to the War Office†:—

"— by the way, you must not be alarmed at mange in this benighted land, nearly every horse in Government or civilian hands which is left on the veldt in winter gets mange; the inhabitants take no notice of it, and it goes with a new coat. We put them through a disinfectant bath which kills it in a few times."

We have referred to the above correspondence at p. 203 of this History in connection with mange on Debility Farms, but its importance, as representing the opinion of an officer closely in touch with the Commander-in-Chief on all horse questions, necessitates its repetition in this section. It must have had the effect of allaying anxiety, and of neutralizing what would naturally be considered the alarmist representations of the veterinary service.

\* The following Remount ships brought mange to South Africa:—

	On	From
"Armenian"	1 Sept., 1900	United Kingdom
"Englishman"	21 Dec., 1900	" "
"South Australia"	22 April, 1901	" "
"Mechanician"	21 June, 1901	New Orleans
"Tactician"	23 June, 1901	" " (Mules)
"European"	11 Aug., 1901	" "
"Cornwall"	24 July, 1901	New Zealand
"Morayshire"	26 July, 1901	Australia
"American"	26 Aug. 1901	New Orleans

This list could be extended, but it sufficiently evidences the way in which remount depots were regularly infected from over sea.

† C of. E Remnts., Appendix F. p. 368.

As a matter of fact, the skin disease affecting our army was true parasitic mange of two varieties, the surface parasite and the burrower, and we never got rid of it until the war was over.

The sources of infection during war are many. Not only were cases of the disease necessarily kept in the ranks, but animals suffering from mange, left behind or captured from the enemy, were freely used and placed amongst our own, and at first, clean animals. It is impossible where blankets are used to prevent infection from spreading, as the same blanket may not be used for the same horse on two successive occasions. Saddle-blankets and saddlery were taken from the affected and placed on fresh horses free from the disease, without any disinfection of the equipment being possible. The men carried the parasites from horse to horse and the trucks in which the animals travelled were prolific sources of infection. Given an outbreak of mange on service or on board-ship, we know of no practicable method by which the spread of infection may be prevented. In saying this it is not intended to convey the idea that no efforts should be made. The rapidity of spread will be considerably lessened by adopting such precautions as are possible in war.

The association of skin disease with debility was a very marked feature, not always the result of cause and effect. A well-known Cavalry Commander regarded debility as the cause of the disease, and believed that horses in good condition could not contract the affection when exposed to contagion. He accordingly did not hesitate to place his own horses in a stable he knew had been occupied by affected cases, and in this way purchased a lesson in the contagiousness of the disease which at once rendered him a whole-hearted supporter of the veterinary view.

The difficulties of dealing with an outbreak of mange in time of peace, so as to guard against the spread of infection, are so considerable that we have no hesitation in saying it is by far the most difficult epizootic with which we have to contend. In war not only is it impossible to control effectively, but the essentials for treatment—isolation, clipping and dressing—are impossible in the Field, and only partly capable of realisation in Stationary Hospitals and Standing Camps. Clipping machines are always a difficulty; frequently of defective material to start with, they are further highly tested by dirty coats and unskilled operators. In fact, for hospital purposes nothing should be used but the power machine, of which there should be numbers, depending upon the size of the hospital, with an ample supply of spare parts, especially blades. Chemical science ought to be able to provide a depilatory which would do away with the necessity of clipping. What an effective agent would mean in the saving of time and labour in a large hospital is incalculable.

A place for clipping should be set apart in Field Hospitals and all hair burned.

The application of dressings needs a large staff of subordinates, but it ought not to be beyond the resources of mechanical skill to arrange for the thorough application of dressings on the same principle as hair brushing by machinery. Dressings are worthless unless rubbed in, and the necessary labour for their application to hundreds of cases is never available at the moment it is most urgently required. The history of the hospitals in South Africa largely centres around the difficulty in obtaining labour for working them, and this will always exist if we depend upon the policy of obtaining local labour for such purely technical requirements as are embodied in the duties of a Hospital Dresser.

The futility of attempting the treatment of mange without a preliminary clipping was over and over again demonstrated; it is worse than useless, for the dressing is of no value and prevents the subsequent clipping of the coat.

For the purpose of applying dressings on a large scale without hand labour the erection of baths, on the principle of "sheep dips," was undertaken. Most of the large hospitals in due course possessed their bath, but the process of obtaining them was slow, as engineer labour, as we have already seen, was not available. The bath was of such a depth that the animal had to swim for a certain distance. Horses did not take kindly to them, and unless arranged as shown in Fig. 6, Plate iii, a good deal of rough handling resulted. As a means of rapidly "dipping" a large number of horses it is of undoubted value, and we place ourselves on the side of those who believe the bath to be a useful adjunct to a hospital. There are many experienced veterinary officers who are opposed to their use, especially in winter, when the shock of dropping into cold water was found to react injuriously on the debilitated. Nevertheless, it takes a long time to dress two hundred cases of mange by hand, while that number can be put through a well constructed bath in a few hours. Sarcoptic mange in the equine is unaffected by baths; such cases must be hand-dressed. It is probable that the value of baths is entirely confined to psoroptic scabies, and that better results would have been obtained had its use been limited to this variety of the disease.

A good bath for disinfecting saddlery and clothing can be made in the Field, by digging a large saucer-shaped hole in the ground and placing in it a sail cloth, such as is used to cover forage or other stores. A bath holding some thousands of gallons of fluid may thus be prepared, and this should exist in all Stationary Hospitals for dealing with clothing and line-gear of mange cases.

Our personal experience was that in the treatment of mange, it was impossible to make a rapid impression where body clothing was allowed. It seems hard on the animal to remove the coat in winter and leave it without body clothing in the open, but experience justified the practice. No

horses died from exposure except such debilitated cases as would have died under ordinary conditions on a wet or cold night. It was, in fact, owing to the experience thus obtained that we found how well animals did without clothing in the open, provided they were well fed. Good feeding is essential in the treatment of mange combined with debility, and the improvement in condition of both horses and mules was not appreciably retarded by the complete absence of clothing. The essential point, however, is that it did them no harm to live in the open, clipped and without blankets, and that was the outcome of an experience of some thousands of cases.

As to the local treatment of mange, it may be safely said that there is no known specific. Everything was tried, and a large measure of success was obtained by all methods of treatment thoroughly carried out. It would be unprofitable to enter into the advantages and disadvantages of each agent so used, but we may broadly indicate that the use of "sheep dip" is worthless for sarcoptic mange; that oily dressings cake and clog in the open; that some of the oils oxidize to such an extent as to form a hard painted surface impossible to remove, and beneath which the disease is spreading vigorously. Ordinary oil, such as linseed, besides drying and caking, has the objectionable property of irritating; this is generally due to adulteration with mustard oil, which inflicts the most acute suffering for a short time after application. Lard oil is bland and unirritating, but difficult to obtain in large quantities. Paraffin and soap solution dressings were largely used, and in skilled hands gave excellent results in psoroptic, but not sarcoptic, mange. The effects require watching, and the mixture frequent incorporation during its application to ensure that it remains in an emulsified state, or separation occurs, and the paraffin blisters.

Major Blenkinsop was responsible for the introduction of the paraffin treatment. The proportions employed by him were as follows:—Two parts paraffin oil, one part linseed oil, two parts soap solution. The preparation of the mixture may be noted. Half-a-pound of soft soap was dissolved in a gallon of warm water; the oil and soap solution were then mixed, and lastly, the paraffin added, the whole well stirred to form an emulsion. The dressing was applied with a body-brush, and again every third day. The animal should be wetted as little as possible, only sufficiently to remove the matted dressing: this the soap enables to be easily done. When the skin is thoroughly dry the dressing is re-applied. The length of period under treatment was about fourteen days.

In chronic cases of the disease, Blenkinsop found that a modification of the above was advantageous. The animals having been washed with a solution of creolin or Jeyes' Fluid were, while wet, sprinkled with pure paraffin from a drop bottle (a quill through a cork), and the oil wiped over the surface with a pad of tow.

Baths of chloride of lime gave good results, but left the skin harsh, and caused irritation if not properly diluted. When applied by hand the men's fingers soon suffered unless precautions were adopted. Baths of corrosive sublimate or arsenic were employed, but appear to have failed to give the best results.

For the treatment of sarcoptic mange, and for those preferring the orthodox greasy dressings and sulphur, a bland unirritating vehicle is necessary, and lard oil meets the requirements; there can be no doubt that the use of common oils should be avoided.

In spite of the difficulties of treating mange during active operations the larger and better equipped hospitals showed good results.

During 1901 the Veterinary Hospital at Johannesburg cured 70% of its 5000 mange cases; in Cape Colony Hospitals, 72% returned to duty out of 4000 admitted; of 27,300 cases in Remount Depots and Debility Farms, treated under Major Blenkinsop's directions during the last ten months of the war, 74% were cured. These figures, collected by different observers at widely different areas of hostilities, indicate that under the unfavourable conditions which prevail in war, including the delay in getting some cases until they are frequently past recovery, or complicated by debility, good veterinary management is capable of returning from 70 to 74% of mange cases to duty.

It may give some notion of the ravages of the disease when we state that it took two and a half years after the war was ended to free the Army of Occupation from mange. The delay was not due to want of thoroughness in treatment, but to recurrences of the disease on the same animals, and to re-infection from buildings and soil.

#### LICE.

Thousands of horses were affected with this parasite; fortunately they do not lead to a condition of inefficiency. Their origin is obscure, and one cannot be surprised at the old notion of "breeding lice," after witnessing a large army of previously clean men infected in a few weeks. Men suffered more than horses from this disgusting pest, and when it is borne in mind that there is no interchange of clothing or blanket in the Field, it is remarkable that infection is so rapid and general.

The origin and spread of this disease has never, we think, been satisfactorily explained. It is not derived from the horses, for not only is the human louse distinctive, but the infantry were infected to an incredible extent. It is astonishing that so little reliable knowledge exists regarding the genesis of this common affection. If men, in time of war, could be kept free from lice, and horses from mange, what untold comfort would result to both!

#### EPIZOOTIC LYMPHANGITIS.

On 30th November, 1900, Captain (now Colonel) Blenkinsop found at Johannesburg two mules and a horse affected with a disease "showing symptoms of glanders, but I am suspicious of ulcerative lymphangitis, known in Syria and Egypt as *Sauraga*." \* He had the animals inoculated with mallein, and they all reacted. This was unfortunate in one respect, as, for the time being, it appeared to settle the question; we now know, of course, that these were cases of mixed infection, and that a mere accident prevented the existence of the disease being then declared. About six months later a report came from a Remount Depot in Cape Colony that some cases of pyæmia, previously cured, had broken out again. It was the recrudescence of these cases which first drew serious attention to the question; the civil veterinary surgeon in charge was emphatic in not regarding the cases as being farcy, owing to the negative mallein reaction. But at that time we had ample evidence to show that glanders and farcy in the mule might not react to mallein, and the cases were accordingly dealt with as if glandered, and destroyed. During the remainder of 1901, cases of "farcy" not corresponding in their clinical features to true farcy, and not reacting to mallein, were met with more frequently, and affected both horse and mule; throughout the early part of 1902 these became still more numerous, but it was not until after the war had ended that it was possible to take the matter in hand for investigation. Dr. Thieler was then able to show that the discharge from these cases always contained the cryptococcus of Rivolta. It was epizootic lymphangitis, the *sauraga* of Egypt, which had been steadily extending for eighteen months.

The disease had previously been unknown in the Transvaal or Free State, but it was known in Cape Colony before the war, where, Dr. Hutcheon † tells us, it was called "Tick Farcy."

It was not until a year after the war ended that matters became extremely serious in South Africa. No less than 455 cases of the disease occurred during 1903-04; and so widely spread had it become that only seven units in the whole of the Army of Occupation were free from the affection. Further, it was increasing; the number of cases at the end of the year was double that at the beginning. While this disease was spreading glanders was decreasing. The campaign against the latter affection was, by the middle of 1904, an assured success, and lymphangitis was at once taken in hand. We had meantime learned much about the disease; it was found that in favourable cases removal with the knife was the only reliable method of cure; the entire lymphatic vessel and its widely separated abscesses being dissected out in one piece. Wounds of extraordinary length were left, but early cases thus radically treated recovered, the percentage of

success being between forty and fifty. The others were destroyed. Recurrence was a prominent feature; some six per cent. relapsed and were destroyed.

It was evident that the most important cause of infection was the method of dressing slight stable wounds, adopted by battery and squadron farriers, of going from one case to the other with a bottle of dressing, and using the same piece of tow or dirty sponge. In this way they carried the disease from one animal to another. An order was published directing attention to the sources of infection, and giving the history of the disease. The order went on to say that a determined effort was to be made to get rid of the epizootic by means of disinfection and inspection. Wounds were only to be dressed under skilled supervision, and fresh dressings used for each. Old dressings were to be destroyed; no wound was to be touched by the farrier's fingers. As by this time stables with concrete floors had been built, the regular disinfection of these with a spray pump was ordered, so arranged that the whole of the stables were disinfected weekly. The pillars, bails and flooring of a standing occupied by an affected case were scorched with a plumber's lamp, and the animals on either side of the affected were regarded as suspects and isolated. Everything depended on the loyal co-operation of the Departmental Staff, and that this was received was shown by the fact that the admission rate soon began to fall, so that for 1904 only one-third of the number of cases were admitted for the last half, as compared with the first half of the year. In addition to the above, the discharge from wounds of all kinds in a unit was examined microscopically once a week, in order to make certain they contained no cryptococci. By the following year the disease was obliterated.

The introduction of specific lymphangitis into the United Kingdom, by remounts sent home from South Africa after the War, will be referred to in the section on "Demobilization."

#### SPECIFIC OPHTHALMIA.

Shortly after the war ended Specific Ophthalmia became a veritable scourge. The disease was seen during the war, about December, 1901, but the number of cases were few. Shortly after the declaration of peace ophthalmia was reported from a Remount Depot in Cape Colony; before the end of the year the disease was found to be widely spread. Specific Ophthalmia appears to have been a new disease in South Africa; neither Dr. Hutcheon nor Dr. Thieler had previously met with it, and we may without hesitation declare it to have been imported with remounts. The conclusion was arrived at that it came with horses from America, in which country specific ophthalmia is common.

The question, however, of origin is not so easily disposed of. 109,739 horses were purchased in the United States between November, 1899, and June,

\* Extract from a report to the P.V.O. of the Army.

† Report of Civil Veterinary Department, Cape Colony, for 1904.

1902; they were received as follows, round numbers being employed:—

Nov., 1899, to March, 1900	1,200
April, 1900, " " 1901	36,000
" 1901, " " 1902	62,400
" 1902, " June, 1902	10,100

Why should the disease only have declared itself after hostilities, in 1902? During the previous year 62,000 horses had been imported from America as against 37,000 in the two previous periods. Why should not some of the 37,000 have shown signs of the disease? We at once confess our inability to answer the question. It might be urged that after the war the general wastage at once dropped, and that the remaining horses, including the 10,100 imported up to June, 1902, lived, instead of dying as those of 1899 to March, 1901, had done. If it could be shown that the disease was subsequently equally distributed between the survivors of the campaign and the new horses admitted to the country between April and June, 1902, there would be something in favour of the view that we did not meet with the affection until some months after the war concluded, as the previous horses died before the disease had time to develop, but we can hardly think this is the case. It is significant that of the units attacked, the Remount Depots, containing the last purchased horses, practically all from the United States, suffered out of all proportion to the others. In one depot no less than 48% were affected, in another 25%.

During the second year after the war over 14% of the horses of the Army of Occupation were affected with the disease, yielding no fewer than 2000 cases. Never has periodic ophthalmia previously existed on such a gigantic scale!

It is a reasonable supposition that when a disease suddenly breaks out and spreads it is due to a contagium; in the case of this outbreak of specific ophthalmia every known method of attempting to communicate the disease by direct inoculation failed. This pointed to an intermediate host, and the fly fell under suspicion, but the use of eye-fringes failed to prevent its occurrence. Apart from the general history there was direct evidence of its infectivity. A remount depot where the disease was rife was broken up, and its horses distributed to two other depots where the disease had scarcely been known. The result was that ophthalmia became an absolute scourge at these depots. Beyond this point we were unable to go, and the agent of transmission remained undetected.

Few cases of the disease were seen in Colonial animals, but at this time only a few existed in the service. Mules did not suffer to the extent of horses, and the South African mule less than the one from the United States. During the third year after the war the disease among horses declined. From 14% admissions in 1903-04, it fell to 7% in 1904-05; with the mules matters remained at a standstill, or were slightly worse. Advantage was taken during this year to ascertain the proportion

of primary and recurrent attacks. These are shown in the following table;—

Of every 100 admissions from the disease—

	Horses	Mules
Primary attacks	50.47 ...	75.62
Second " "	32.23 ...	16.80
Third " "	11.00 ...	3.36
Fourth " "	4.40 ...	1.68
Fifth " "	1.10 ...	1.68
Sixth " "	.62 ...	.84
Seventh " "	.15 ...	—

During the fourth year after the war the disease became still further reduced, and eventually passed away. It is greatly to be regretted that no definite source of infection was discovered. It was a sound measure to treat the affection as microbic, and it is possible that the stall disinfection, so thoroughly practised for Epizootic Lymphangitis, was one of the means by which the affection was subsequently abolished. The causes of the trouble, and its ravages after the war among a body of animals previously comparatively free will ever remain a mystery.

#### TONGUE DISEASE.

This disease was entirely new to the Veterinary Service. It is characterised by the formation of vesicles on the tongue, and sometimes on the lips. The vesicles inside the mouth, instead of running a simple course, ulcerate, converting the tongue into a complex of ragged ulcers with sloughing masses of the tongue tissue and intense fetor. Acute cases died from starvation, as feeding was impossible, and in those examined post mortem the ulceration was found to extend to the back of the tongue and fauces, with deep destructive necrosis of tongue, soft palate, and even the cheeks. Attempts were made to reproduce the disease by inoculation, but failed, yet it can hardly be doubted that it was contagious. Few animals escaped an eruption on the lips resembling variola, though fatal cases occurred in which there was no such eruption.

Nothing was seen of the disease until May, 1901, and at that time it appeared to be widely distributed over Cape Colony and the Free State, causing a relatively high mortality. Veterinary hospitals and remount depots were affected, and also units in the Field. Of its existence in the Transvaal at this time there is no record, but the disease was known there, as it is recorded by Dr. Thieler, who had observed several outbreaks before the war.

During 1902 very little was heard of the disease, and the cases which occurred were milder. It is a subject for regret that more information of a definite character was not obtained regarding this affection, which in some respects resembles vesicular stomatitis, though infinitely more acute than this disease as seen in Europe. The inability to convey it by inoculation and the mortality are also in great contrast to the benign disease. The affection caused widespread inefficiency during the winter of 1901.

*BILIARY FEVER.*

This disease in South Africa was made known by the work of the late Dr. Hutcheon in 1883, who found it was prevalent in the Cape Peninsula, along the East Coast, and for a hundred miles inland, later on he observed it had spread all over the South African Colonies.

In the Cape Peninsula nearly every imported horse was found to suffer, and, it may be added, dogs also. It was not the first time Biliary Fever had been met with by the Veterinary Department of the Army, for in India imported Australian horses suffer, likewise horses imported into Egypt.

The horse of South Africa does not suffer from Biliary Fever, he has an acquired immunity, though his blood contains the organism, and when inoculated into a susceptible animal it conveys the disease with certainty. The cause of biliary fever is a parasite in the red blood cells, closely allied to that met with in man in malarial fever, and in the ox in "red water." Thieler worked at the disease during the war, and a year or so after its conclusion proved that the source of infection was the red tick found principally in the region of the fundament. The tick is picked up while grazing; abundant observations show that on the high veldt stabled horses are relatively immune, though this was not observed by Hutcheon in the coast districts. During the campaign a vast amount of inefficiency resulted from this disease, for all imported horses were liable to attack. It is more prevalent in the early spring and hot season, the period at which the campaign broke out, and horses so attacked are rapidly rendered useless. It is not known how many of the thousands of sick and debilitated horses were affected with the disease, but a very high percentage. Had our knowledge of the affection been as complete at the beginning of the campaign as it was subsequently, it is difficult to see what preventive measures could have been adopted. To keep animals free from ticks is a council of perfection under service conditions. The mortality from the disease a year after the war was 16%: during the war it was infinitely higher.

*OSTEO-POROSIS.*

This disease appeared in Argentine horses imported to the Cape in 1898, and was described as such by Lieut. (now Major) A. H. Lane, A.V.D. Nothing more was heard of it until 1904, though isolated cases had occurred from time to time among the civil horses in the Cape Peninsula. In the latter year the cases became so numerous in Cape Town and its suburbs, that a special inquiry was instituted by the Cape Veterinary Department. In the language of Dr. Hutcheon, it had "become the greatest scourge affecting horses in the Peninsula." In the early part of the same year a large number of military mules at Middleburg Cape, a long distance from Cape Town, were found to be

affected with lameness following on wet and cold weather. This was attributed at first to rheumatism, but as the number in hospital gradually rose to 250, it became evident that something more serious existed. An inspection of these animals showed the presence of osteo-porosis; the lower jaw was thickened in many cases, and deformity of the face existed. Some animals in attempting to rise would tear away the joint ligaments from their insertions. A few post mortem examinations decided the nature of the affection. Fortunately it was localized. The horses in the same station were generally unaffected, so that the food and water appeared to be above suspicion. Notwithstanding, a change in diet, especially to green food, was found to be productive of marked benefit among these animals, though Dr. Hutcheon was unable to confirm this view among the civil animals under his care at Cape Town. The history of the disease points to importation from the Argentine and the United States; it was known in Africa among imported race-horses before the war. Whether, as Lieut. Lane held, it was purely a dietetic disease dependent on a shortage of lime in the food was not settled. Personally we regarded it as microbic.

*PLEURO-PNEUMONIA.*

Throughout the campaign pleuro-pneumonia among the transport oxen was always present; 13,700 cases were reported between April, 1900, and February, 1902, and the majority of these either died or were destroyed. These numbers cannot represent the total number of cases occurring, for the disease was widely spread before the war, and probably no column escaped infection. As a means of keeping the disease under control inoculation was practised. It was impossible for this to be carried out by skilled labour; every man who has been with cattle in South Africa considers himself capable of inoculating. These people frequently employed putrid serum and decomposing lung, the latter actually introduced into a slit in the tail and bound in position. The losses from inoculation carried out under these conditions was considerable; even with the greatest care some loss will be experienced, for the local reaction is frequently intense. A source of infection, not only of pleuro-pneumonia, but of other diseases, was animals abandoned by the enemy in order to be picked up by ourselves. It was an artifice justifiable in war, and a trap into which commanders and others frequently fell. No captured animals should be placed among those of the army until inspected and found free from disease.

The general principles of dealing with a threatened outbreak of pleuro-pneumonia in the Field have already been narrated at p. 59. The collection of serum for this work should invariably be carried out by a professional man; no one else appreciates the importance of cleanliness, freedom from blood and fragments of tissue.

**CATTLE PLAGUE.**

The outbreak of this disease in 1901 has received notice at p. 206; it was necessary to introduce the subject at that point in order to give a clear picture of the difficulties occurring from month to month during the campaign. We have already seen the condition of affairs resulting from the outbreak of Rinderpest, and the losses among the transport cattle from this and other causes down to December, 1901. By this date the control of the disease was well in hand, and the general death rate had fallen to 11%. The following table shows the mortality among oxen from all causes for 1902:—

	Strength	Deaths
January	63,800	9.27%
February	68,700	4.69
March	74,700	4.83
April	75,500	4.42
May	74,300	4.62
June	69,300	6.31

It is not possible to say what proportion of the deaths in the table were due to Rinderpest, but the number would be relatively small after January, as by December most of the animals had been inoculated.

Sufficient for our purpose has been stated, at p. 207, of the difficulties of controlling a disease like Rinderpest in time of war. The great thing was to establish inoculations as early as possible, and the Serum Stations which were opened have already been noticed. The material used for inoculation, pending the lengthy process of serum production, was the injection of rinderpest bile, either in a pure condition, or after being mixed with glycerine.\* The point is still unsettled what risk attaches to inoculation with pure bile.

It will be remembered that bile inoculation was the discovery made by Professor Koch during the outbreak of Rinderpest in South Africa, in 1896-97. He collected the bile from the sixth to the eighth day of the disease, and employed 10 c.c. as a dose which gave a temporary immunity of four months or less; such a period is of the greatest value in a campaign, and if the bile inoculation could be kept up every three months protection would be maintained. The question of whether pure bile can produce the disease is even now not settled. Turner and Kolle deny it, but the late Dr. Hutcheon, of Cape Colony, and his veterinary staff generally, were opposed to the use of pure bile, which they regarded as unsafe. Bile can be rendered free from any chance of producing Rinderpest by mixing it with glycerine. Glycerine destroys the virulence of Rinderpest blood, but not the immunising substances, and glycerinated bile, in 20 to 30 c.c. doses, was used for the control of the disease in Cape Colony, pending the production of serum, while in

\* Two parts of Bile (preferably a mixture of biles) to one part of Glycerine, well stirred, and left to stand for eight days. In cases of urgency it can be used in 48 hours.

the Free State pure bile, in 10 to 20 c.c. doses, was largely used. Unfortunately there are no figures available by which the value of these processes might be compared. The late Lieut.-Col. Flintoff spoke enthusiastically of the benefit of pure bile inoculations in dealing with the disease in the Free State. Dr. Turner\* denies that if collected at the sixth to eighth day of the disease it ever produces Rinderpest. Kolle found that bile collected at the third or fourth day may produce the disease, and it seems not unlikely that some of the differences of opinion may be due to the period at which the fluid has been collected. For instance,—during the campaign, when bile was urgently required, it must frequently have happened that the animal was destroyed too early in the disease. It appeared to those responsible for dealing with the epizootic in Cape Colony that glycerinated bile gave no risks, and it was accordingly adopted.

The disadvantages of temporary immunity led, very early in rinderpest investigation, to the search for a better and more permanent method. Turner and Kolle devised that now in present use, known as the simultaneous method of serum and virulent blood. The antidote is injected into one shoulder and the poison into the opposite one. The animal passes through a febrile reaction and obtains immunity, the loss from the reaction being under two per cent.

The presence of Dr. Turner at Pretoria during the epizootic was of great value; together with Dr. Theiler, he established a Serum Station, and some thousands of doses of serum were produced, but the outbreak was principally controlled by Koch's bile method, as an army cannot wait three months for serum. The bile method in the Transvaal was divided into two stages: first, the glycerinated bile, which incapacitates an animal for about ten days, followed by a pure bile inoculation, which conveyed a long, or, as some think, an everlasting immunity. The Transvaal experience was that pure fresh bile should not be employed in the first instance, as it tended to intensify the character of the disease in those animals already infected, while its immunising effect was too slowly developed to protect healthy animals left in contact with the sick. Jugular injection of glycerinated bile conveys earlier immunity than a subcutaneous injection; in the case of animals urgently required for transport purposes in an infected area, jugular inoculations were practised with good results.

The work connected with Rinderpest on the various Transport and Supply Farms has already been referred to at p. 273.

**SAND COLIC**

The occurrence of sand colic among horses and mules on service will never be capable of entire prevention. The amount of mud and sand taken up with the water and food in a day would be astonishing if it could be brought together. Whether

\* Now Sir George Turner.

animals graze or are hay fed in the lines, they are compelled to take in a certain amount of adhering sand. Fortunately the majority of horses get rid of it regularly with the fæces, but others store it up, and it then becomes a most fruitful source of trouble and mortality. The prevention of sand accumulations among animals living in the open should be one of the constant cares of the commanders of mounted units, and a great deal may be effected by cleanliness in feeding and watering. If blankets are in use the hay may be placed on them. Animals who deliberately eat sand should be muzzled after feeding, and extra salt given with the rations. Watering from a pond should, where possible, be effected by buckets, for the slime and bottom generally are turned up by the first animals which enter; watering from a running stream with a rocky bottom is free from objection, but all rivers in flood after heavy rain are sure to be charged with a considerable amount of mud in suspension, and for this there is no practical remedy on a large scale.

Despite every effort a considerable amount of sand and mud will be swallowed, but care will afford protection against preventable ingestion.

#### DEBILITY.

No reference to the diseases met with on a large scale during the war would be complete without mentioning the most common of all others, debility and exhaustion. The causes for these have been sufficiently studied in the body of this history; we have traced the origin to the semi-starvation diet allowed, and subsequently to the employment of hopelessly unfit horses for the hardest work animals are ever called upon to perform. It is unnecessary to labour the point any further. That there was contributory negligence on the part of regimental commanders has been repeatedly shown, that there was neglect as the result of a total ignorance of the animals' requirements has equally been demonstrated, but beneath all this lies the one solid fact that, after the trained horses of the Cavalry had been utterly destroyed by starvation, there was nothing to take their place but raw, untrained, soft, weakly, underfed creatures, themselves already sick. These, we have seen, filled the ranks from the advance from Bloemfontein in May, 1900, onwards. It is not to be supposed that all the remounts during the remaining two years of the war were equally as "soft" as the above; desperate efforts were made to get some of them into "condition" for work, and as we have seen, in skilled hands, success was obtained, but the time allowed was never sufficient for the purpose generally, and, as mentioned at pp. 188-9, nothing but a suspension of hostilities in 1901 could have effected any all-round improvement. Fresh drafts of officers and men for the regular forces, and an entire change in the Yeomanry and Colonial contingents, were another and unavoidable cause of inefficiency, for these had

first to learn their work before they could practise it. Finally, the working out of horses to the last possible effort was a proceeding of incalculable harm, and one which was not always under regimental control. No difficulty exists in finding adequate explanation of the fact that tens of thousands of horses were rendered useless after a few days' service; the sole difficulty is in furnishing a reasonable explanation of why a practice so obviously destructive was persisted in in the face of all experience and common sense. Into this question, as we have said elsewhere, we cannot enter, but it would appear that the power and endurance of unfit horses were either not understood or were over-estimated. Lord Kitchener's examination before the Royal Commission threw no light on the matter, for the question does not appear to have been raised, perhaps for the reason that the scope of the Commission was confined to the period between the beginning of the war and the occupation of Pretoria.

The utility of thousands of horses was limited to a few days, in many cases a few hours, but the general rate of wastage for the war was 25% a month, so that every horse with the columns was replaced three times in the year, or four months as the mean duration of effective life, whereas it ought to have been nearly thirteen. The main cause of this wastage was debility, and from this alone thousands of horses every month entered hospitals or debility farms, see p. 186.

It has been mentioned, at p. 137, that when animals are reduced in consequence of hard work and insufficient food their recuperation cannot take place on corn; if the material is not assimilated it lies in the intestinal canal and undergoes little or no digestion, and, in fact, frequently causes irritation. What is required for such cases is grass, the natural diet of horses; but this is only obtainable in South Africa during the rainy season. What remains after that is a desiccated stem and leaves, deprived of their natural juices, and as useful, at the end of winter, as thatching for restoring the debilitated. Green crops of almost any kind, but especially barley produce an astonishing improvement in debilitated horses, and the cultivation of these crops, both at debility farms and hospitals, was established as a routine measure late in the war. It is obvious how difficult it was to obtain the very food on which the recovery of these animals depended. The weakest and most constitutionally delicate succumbed, generally as the result of a cold night or heavy rain-fall. Those with a little more life left in them would be found down in the morning and utterly unable to rise of their own accord. They required to be lifted bodily upon their legs, and the warmth of a generous sun did the rest. How many died on farms through no help being at hand to assist them on to their legs will never be known.

The drafting of horses from one debility class to another is an essential feature in management; it is no use putting the strong and the weak together; all weaklings must be together, all those improving

form a second class, while a first class is represented by those fit for grain feeding, and from which selections are made once or twice a week for transfer to Remounts with a view to subsequent issue. Without some such rough classification farms are not doing their best work; horses get overlooked, and, worst of all, the weak and strong are thrown together. Classification and grouping are the two cardinal points for the Remount Officer to attend to, and while this is taking place the Veterinary Officer should be inspecting for infectious and contagious diseases, and weeding out any which appear to be hopeless and show no sign of improvement. This work cannot be hurried, and it is desirable that the classes should be made as small as possible for convenience of inspection.

A good supply of clean drinking water is essential; if this does not already exist in the paddocks, an officer should be deputed to see the various classes taken to water in mob formation, for no one else will do the work conscientiously. It is astonishing how rapidly horses adjust themselves to their new surroundings when in large numbers. If they have to be taken to water twice a day, they will be found collected awaiting the event; the first day or two may lead to an attempt at a scamper, and consequent falls from sheer muscular weakness, but they soon come into line, and solemnly walk off to water or grazing in a long drawn out procession conducting themselves with perfect propriety. Any attempt to hustle debility cases by trotting to save time should lead to the immediate dismissal of the offender. The animals must walk, be handled quietly, coaxed and encouraged; whips should be unknown. Three or four mounted men, skilled at the work, will conduct some hundreds of horses, one riding at the head, another at the tail, and one on either side. Every man who can ride will not be a stock-rider; we learned much of this work from our over-sea colonial brother, though his methods are frequently too rough and boisterous for horses in a state of debility. With water, grazing, and constant supervision a month will see astonishing improvement even in the worst cases; three months should see the majority of the horses in the ranks.

The man whose perseverance and attention successfully manages a debility farm, and keeps up a regular supply of suitable animals for the Remount Depot cannot be too well rewarded for his work at the end of the campaign. The secret of success lies in the eye of the master, and that must be kept focussed on its objective for as many hours as the sun is above the horizon.

No attempt has been made in this outline to deal in detail with the question of debility farms and their management. In the above sketch almost ideal conditions have been assumed. In practice the reverse will be met with, and the ability of those in charge will be shown by their adaptability and resourcefulness in making the best of existing conditions. The first step is to arrange

for water and grazing; then classification, grouping, and regular inspection; after these, attention must be paid to manger construction, and shelters for the worst cases. The results following on this systematic organisation will be astonishing, provided the officer in charge thinks of his horses all day, and dreams of them at night.

Where debility farms are under no organisation, the state of affairs which will result is that described at pp. 137 and 202 of this History.

#### WOUNDS AND INJURIES.

The wounds and injuries which occur to the mind as being associated with war are those due to firearms. As a matter of fact they represented during the South African War quite a minor and relatively unimportant part of the trouble. Readers of this History must have been impressed by this fact. We are anxious, however, not to press the point too far, for a very different tale would have had to be related had the British Forces in South Africa been engaged by numbers equal to their own, and as numerically well-equipped with weapons of destruction.

In European Wars the proportion of horses hit is generally greater than that of men. During the wars, 1866 to 1870-1, for every 100 Cavalry soldiers killed or wounded in action there were 140 horses, and for every 100 Artillerymen there were 130 horses. In the operations at Mars la Tour, confined to Cavalry against Cavalry, the three German Cavalry Divisions lost in hand-to-hand fighting 14·7% of their men, and 16·3% of horses. The fire losses occasioned by Cavalry charging Infantry may be illustrated by the losses of the French Cuirassiers at the Battle of Wörth, where 30% of the men and 57% of the horses were lost; the German charge against Infantry at Bapaume resulted in 10% of the men and 24% of the horses falling.\* It is evident, therefore, that the relatively small proportion of horses hit in South Africa does not represent the normal state of affairs, though it is probable that in the future cover for horses will be far more carefully taken. The explanation of the preponderance of horses hit over that of men is, of course, due to the larger target. It is not only higher, but wider and infinitely deeper than that of a man. When exposed broadside on to a fire, the effect is greatly increased, for not only is the target many times larger, but a bullet passing through the cavity of the chest or abdomen has but little of its velocity removed, and may continue on its way and pass through two or three other horses, depending upon the range at which it was fired.

\* "The Loss of Horses in War," Veterinary-Captain F. Smith.—*Journal of the Royal United Service Institution*, Vol. 38, 1894.

#### ARTILLERY FIRE.

Fire injuries are grouped into those produced by artillery and those caused by infantry. The trifling losses occasioned by artillery fire in South Africa produced a feeling of contempt for all but its moral qualities. For instance, many thousands of shell were fired into Ladysmith, but the losses both among men and horses were small. On 6th January a battery stood in the open and was shelled from three sides, and had but three men and fourteen horses killed and wounded. We have seen at p. 67 that over 20,000 shell were fired into Mafeking during the siege, yet the total number of animals hit was thirty out of an original strength of roughly 700. The strength diminished considerably from February onwards, so that the percentage hit would be higher than that indicated, nevertheless it was insignificant. The explanation of the small loss from the Republican Artillery was due to the fact that they favoured common shell. Shrapnel, as used by our artillery, is most destructive, and we have noted at p. 67 the number of bullets lodged in the body of one horse exposed to this form of fire. At p. 46 also we have seen the recorded effect of a 40-pounder shrapnel fired into Ladysmith, which killed or wounded twenty-four mules and four men. It would be absurd to discount the destructive effects of artillery fire from South African experience alone. In a European War with larger masses engaged, and innumerable guns pumping in iron from quick firing guns, the destruction, as shown by the recent war in the Balkans, is terrible.

Shrapnel fire kills or wounds with its bullets, common shell by the bursting of the projectile. In this latter case, if the shell fails to kill, by disembowelment or the removal of head or limb, quite a crop of jagged wounds may occur as the fragments scatter. These may be confined to the skin, or portions of the underlying muscles may be torn away. The horse fortunate enough to receive only grazes from flying fragments may be some little time under treatment, owing to the sloughing of the flaps, for the bruising is considerable. We have seen this was the case in Mafeking, where the wounds became indolent and sloughed; but there were two factors at work here, the pounding of the tissues and animals on siege rations, see also p. 67a.

#### RIFLE FIRE.

The bullet employed by the Republican Forces was chiefly the modern projectile common to all European Armies; but bullets of greater calibre were frequently used, especially the Martini. The long, narrow, present-day bullet is not devised for the purposes of humanity, but for its increased range and accuracy, and for the larger number of rounds which may be carried for a given weight. Incidentally, it is more humane, and unless a large bone be struck or vessels severed, no immediate, and frequently no subsequent, inconvenience results from

the muscular wounds it produces. The bullet, by being made long and narrow, offers the least resistance to its passage through the air, and so long as it is in equilibrium it maintains its long axis parallel to its line of flight. At extreme ranges there is a tendency for its centre of gravity to become displaced, and the bullet may make half a revolution and strike base foremost; far more serious, from a surgical point of view, is the fact that the projectile may make one quarter of a revolution and strike side on. This will produce a wound of the most extensive nature.

There was little learned about the behaviour of narrow bullets during the war which had not been arrived at by experiments on the dead body during peace.\* The destructive effects of the bullet depends upon its velocity and the resistance offered to its passage by the various structures of the body. The opposition offered by a purely muscular mass is relatively small, so that the projectile passes out, or ploughs its way for a considerable distance into the soft parts of the body. With bone the matter is different, those offering very little resistance, such as the blade of the scapula, are punched and the edges starred; with dense bones, such as those of the limbs, the resistance is considerable, the effects are consequently almost explosive in violence and the bullet partly breaks up. Pulverising effects may also be met with in the semi-rarified bones of the knee and hock joints, doubtless owing to the depth of tissue to be traversed.

In muscle pure and simple the path is narrow; there may be a channel little, if any, larger than the bullet, the path being identified by the trifling muscular hæmorrhage. The length of the channel depends on the part struck; in the cavities of the chest and abdomen the bullet may find exit, with sufficient remaining velocity to enter one or more horses. In the muscular masses of the hind quarters the projectile may pass across and be found under the skin of the opposite side; when the animal is hit in purely muscular masses the bullet travels an extraordinary distance, and far out of reach. There may be two or three such wounds in the same animal which cause no inconvenience if vessels or bones have been avoided. The frequency with which these bullets twisted and turned in their course is noted at p. 17 d.

Wounds from ricochets are frequent, and may be extraordinarily severe; this, of course, is due to the amount of distortion the bullet receives before striking the body.

One of the greatest difficulties in practice is to determine *where* the horse is hit: the surface of the body has to be carefully searched to enable a minute cleanly punched hole to be discovered, the size is out of all proportion to the bullet, for the skin is elastic and stretches to allow the projectile to enter. We may be directed in our search for the point of entry by the existence of a little coagulated blood

\* "The effect of the Lee-Metford Bullet on the Bones of the Horse." Veterinary-Captain F. Smith, *Journal of the Royal United Service Institution*, Vol. 38, 1894.

matting the hair; beyond this there is nothing to show, though the most extensive destruction may exist within. If the bullet gains exit the skin opening is larger and generally everted.

Injuries to the chest or abdomen are either fatal in a short time, or, if they have failed to find a vital spot, they cause no inconvenience. Such happy results are more common in the chest than in the abdomen, where a bullet can hardly fail to catch something in its course, generally the intestines, resulting in many and widely separated perforations, depending on the position of the convolutions at the moment of injury.

Injuries to the hoof present a remarkable character. When a bullet strikes the wall, the horn fibres open to admit it and at once close. They behave exactly as a piece of rubber does when fired into. Not a trace of blood may mark the spot of entry or exit, but merely a slight mark or graze of the horn, as if it had been in contact with a sharp pointed piece of rock, yet the structures within may be pulverised. This class of injury, fortunately rare, will always be a difficulty in practice; even a larger bullet, such as the Remington, may strike the hoof, enter, and leave practically no trace of its presence within.

The great lesson learned during the war in connection with bullet wounds was that of non-interference. There is ordinarily no reason whatever why a bullet should not remain in the body; with exceptions to be presently mentioned it causes no inconvenience. Probing is useless and dangerous, the clot of blood sealing the orifice is thereby removed, and whatever is introduced into the channel only aggravates what may be a perfectly simple wound. Injuries to the face involving damage to the molar teeth form an exception to non-interference, for the broken fragments of tooth should be removed and any loose portions of bone. Injuries below the knee and hock are frequently penetrating; if such is not the case the bullet may be felt, and should be removed, as it may prove a mechanical impediment to the working of the parts. If out of harms way it should be left alone. The extraction of bullets with the forceps supplied at the early part of the war, was a surgical operation far more destructive than the bullet; it converted a simple into a complex wound. A bullet near enough to the surface to be grasped may be removed with dressing or other forceps, though it is infinitely more tenacious of removal than this statement may imply.

When a long bone is hit and pulverized, there is no question of the extent of damage, for the part feels like a bag of marbles; but some joints, notably the knee and hock and the foot, may be pulverized within without any destructive feel being imparted on manipulation. Wounds of vessels are rapidly fatal when large trunks are involved, otherwise the surgery of the vessels is less important than in man.

There is always a difficulty in the Field in obtaining anything like exact information regarding fire

injuries to animals; the man knows that his horse has been killed or seriously injured, and that it either fell at once or shortly after being hit. But where the injury occurred he is naturally ignorant, for the reason previously noted. When neither man nor horse return, the animal may or may not have been hit, but have passed into the hands of the enemy. It is only in siege operations that any opportunity exists for making an expert examination of each case of injury, yet a knowledge of the percentage of horses hit, and the proportion of fatal, serious and slight cases is of the greatest interest. In the Field, the more seriously injured animals are unable to move, and may consequently be returned as missing instead of wounded. Where large vessels are cut they bleed to death on the spot, and if the long bones of the limb are pulverized they remain where they are. Consequently, it is only those horses able to walk after being wounded, or still capable of carrying their riders, which subsequently find their way into a Field Hospital for treatment, and this no doubt has led many to regard the narrow bullet as producing insignificant results on the horse.

In the siege of Mafeking 79 bullet injuries were inflicted on horses, of these 52 died, 15 were destroyed, and only 12 recovered (see p. 67). All the injuries were produced by the Mauser rifle, and a weapon which can inflict 85% of fatal or incurable cases cannot be regarded as ineffective. Head's results\* were much the same. The regiment he was with had 163 horses hit, and of these 77.3% were either killed outright or had to be destroyed.

The position of injuries on the body is information of the greatest interest, but, unfortunately, with one exception, no exact records are available. With man it is known that injuries of the upper half of the body are more frequent than those of the lower half, but we have very little of an exact nature to determine these questions for the horse. Theoretically his trunk must be hit more frequently than the limbs owing to the considerable area it offers. We are indebted to Captain (now Colonel) J. Moore for an exact classification of his wounded at the action of Ramathlabama (see p. 64 of this History). Of 300 horses present, 83 were hit, or 27%. Thirty-nine were killed outright or unable to leave the Field, and forty-four were subsequently treated for their wounds, of which the following gives the situation:—

Injuries to hind limbs and quarters	23
" " fore " " "	6
" " trunk " " "	11
" " head " " "	4

Hits in the thigh and stifle were more frequent than elsewhere, and the excess of hind wounds over wounds of the fore part of the body may, in this case, be explained by the force having to retire. Only one animal was hit in the foot.

\* *Op. Cit.*

The essential fact revealed by the War was the absolute necessity for adopting a conservative and expectant attitude in the treatment of rifle injuries.

#### VELDT SORES.

This class of sore was found among the horses in the Field, especially during General French's campaign on the Pongola (related at p. 158b.). From the description given of it as an indolent ulcer affecting the limbs it would appear to resemble Bursattee. Others believed it to be caused by the irritating nature of the mud in which the animals were standing for weeks, but we have seen (at p. 166) that it occurred in the almost waterless northern territory. The matter is one on which we have little information, and apart from the above-mentioned outbreaks the disease did not generally appear among the horses in the Field.

#### INJURIES FROM LIGHTNING.

These were very common, or rather deaths from lightning stroke occurred probably every week during the wet season. A team of bullocks or mules, or three or four horses, might fall at a single stroke. The total loss of life from this cause throughout the campaign would be quite considerable, but records are wanting. It is remarkable how little there is to show on the surface of the bodies. Doubtless the hair and pigment of the skin conceal the tracings found in man, but there is frequently scarcely any singeing of the hair to indicate that the animal has been struck.

#### VELDT BURNS.

These were caused by the disastrous fires that occur, generally through carelessness, during the dry season. The fire spreads with extraordinary rapidity, and animals tied up on the picket line have very little chance of escape. In such cases the feet and limbs in severe cases are burned to such an extent as to demand the animal's destruction. If retained under treatment large areas of skin slough off, exposing the parts beneath, and indicating the hopeless results of further efforts.

Any camp in grass lands which, during the dry season, is to be occupied for longer than a night, should have an eight-foot clearing made all around it.

#### SEPTIC VILLITIS.

This class of injury was very common in the thorn country, see p. 166, where it caused a serious amount of inefficiency and subsequent loss from septic infection. No preventive measures suggest themselves. In the matter of treatment, the thorns (known in South Africa as "Wait-a-bit," and growing on a variety of acacia) are most difficult to remove; they break off flush with the skin and

produce acute inflammatory trouble. In India, poultices of the earth thrown up by the white ant is employed to extract thorns, and in tropical and sub-tropical operations this remedy might be employed.

Injuries resulting in the serious class of affection known as Quittor have been sufficiently dealt with at p. 244; those due to Heel-gall have been described at p. 274; Sore-backs at p. 245.

#### POISONOUS PLANTS.

South Africa is not only the home of Epizootic diseases but also of a large number of poisonous plants, of which, even at the present day, very little is exactly known. Animals which have to gather their keep in the open are naturally much more exposed to infection than those stable fed, and throughout the War the loss occurring to all classes of animals from grazing was enormous. Not a column, practically not a unit, escaped from more or less loss. Thirty or forty cases of tulp or other vegetable poisoning in a few hours were by no means unknown. The consequent inefficiency was considerable, especially during the rainy season, at which time these plants spring into life and cannot be distinguished in their early growth from ordinary vegetation, especially is this the case with "tulp," which resembles shoots of young grass. Noxious vegetation is consumed by the new comer, but animals reared on poisonous pasture learn, apparently from experience, what to avoid, though this is by no means invariable.

The symptoms produced by poisonous plants may roughly be grouped into those which set up extreme gastro-intestinal irritation, for example, tulp, ink-bush, oleander, and those producing nervous symptoms, frequently indicated by tetanic convulsions, such as *Chailletia Cymosa*,\* "Gift Blaar," "Klimop," *Cotyledon Ventricosa*,† "Slang Kop" and "Dronk Grass," the latter producing giddiness and symptoms resembling alcoholic poisoning. Nor does the above list by any means include all which are known. There are cumulative vegetable poisons which produce cirrhosis of the liver; others which cause laminitis in cattle, disorganization of the feet, bone and joint disease. Nor need we be surprised at these extraordinary local effects when we remember the action of Indian "mutters" in producing spasm of the larynx in the horse. It is not with the latter group we are concerned in this section. Only those poisonous plants which act rapidly and produce tympany and acute abdominal pain were recognised as poisonous, and "tulp" and ink-bush were the chief offenders, tulp predominating. There are some thirty-seven varieties of tulp, of which the one bearing the purple flower is the most poisonous. That it is consumed readily

\* Local name not known.

† Idem.

by starving animals after months of drought is not to be wondered at. The effects are shown in a few hours—diarrhoea, acute tympany and pain, great collapse and rapid dissolution are the prominent features. Head\* also noted the presence of a peculiar sour, musty smell of the mouth. There is nothing diagnostic in these symptoms, but the fact that a large number of animals are simultaneously affected tells its own tale. There are districts notorious for infection, but all low-lying ground in the neighbourhood of streams, rivers and water courses is liable to contain the plant. In spite of this well-known fact, it was remarkable how little attention was paid by many of those in authority in the selection of grazing areas. Animals were permitted to graze when waiting their turn to ford a river. It was natural to take advantage of this delay, often a matter of hours, yet no worse site could have been selected, though the high ground in the neighbourhood would have been practically free from danger. Over and over again disastrous results attended on the neglect of the simple precaution of selecting grazing areas; orders were published, but on service these are rarely read, or they are lost in transit, or put away and forgotten under pressure of urgent work.

The mortality from tulp poisoning is very high, though early and energetic treatment will save many. The most urgent matter is the relief of tympany, and this can be effected by puncturing the intestines. Of 172 cases punctured by Captain (now Lt.-Colonel) Dunlop Smith, 167 recovered. Of 72 animals not so treated, during his absence, only 14 recovered. So urgent are the symptoms that no delay must be permitted in the matter of puncturing the bowels. We have seen (at p. 96) that this had to be done by Lieut. (now Major) F. W. Hunt at a time when the force was closely engaged with the enemy. To clear out the intestinal canal as early as possible is imperative; in the hands of Captain Head, A.V.C. (R), the employment of Eserine met with good results.†

#### DISPOSAL OF THE DEAD.

The area of operations was strewn with the carcasses of animals. An account of this at its worst stage is given at p. 41 d. The number of dead removed from the water of one section of a single river is mentioned at p. 118 d. It is impossible to give an adequate picture of the appearance of all camps and bivouacs, especially during the early stages of the war, when the troops were operating in large masses. The dead lay everywhere, and there was no means of coping with their disposal, for no labour existed for burial and no fuel for burning. As the various large centres became occupied it was evident that some effort must be

made to collect the carcasses dotted all over the neighbourhood, for they lay in the water sheds, and with the advent of the rainy season extensive pollution of water supply was certain.

At Kroonstad, for instance, where hundreds of carcasses lay rotting, they were collected on an elevated piece of ground, laid side by side, and a deep trench dug around so as to cut off the water which, in the wet season, would have rushed through to the neighbouring stream. In this way no surface water could escape excepting by filtration. As an economical means of rapidly disposing of the dead this recommends itself, but is open to the objection that the putrefying mass is above the ground. The fine dry air of South Africa rapidly desiccated the remains, and later, in the case of Kroonstad, Lieut.-Colonel Flintoff introduced the South American method of using dried animal material as fuel. The dried, mummified remains were easily ignited, and one carcass served as fuel to consume another. The whole in this way were completely burned. It is obvious, however, that no such method as this is applicable for some months, until the carcasses are dry: in the meantime the air is poisoned.

Burial as a means of disposal naturally suggests itself, but digging a pit to hold a single horse is a big undertaking, one to hold fifty or a hundred bodies is an immense task, requiring a small army of labourers. Nor is there always a suitable site for such a burial ground in the vicinity of the carcasses, so that these may have to be dragged by hand considerable distances. Where burial is resorted to, there should not be less than three feet of earth covering the bodies; the animals must be laid on their backs, as the most economical method of packing, and fitted in closely. The stifles and elbow joints must be cut across to allow the limbs to fall; and the abdomen must be opened.

On the scale with which destruction had to be carried out in South Africa, there was practically no method of rapidly dealing with the dead; 250 animals destroyed in a day from one hospital was by no means unknown. Long before these could have been buried, even had the labour existed, other batches would have been awaiting disposal. Destructions have one advantage over deaths, and that is, the most favourable site may be selected, and no dragging of carcasses is necessary, but in all cases the mass should be isolated from the general surface of the soil by means of a trench to prevent the escape of surface water.

The Secretary of State for War was addressed in Parliament on the question of cremation being resorted to in South Africa for the disposal of animal carcasses. The suggestion was a natural one from those unfamiliar with the fact that the country contains no fuel. An incinerator, however, was erected in connection with the veterinary hospital of Pretoria, early in 1902. Some months were occupied in discussing the matter and in getting out plans and estimates; finally, at a cost of £300, one was produced. Its working capacity was fifteen

\* "The Wear and Tear of Horses during the South African War." *Journal of Comparative Pathology and Therapeutics*, 1903.

† *Idem*.

horses a day, at a cost, it was said, of about 1 cwt. of coal, exclusive of that necessary for the first heating of the kiln; including this, it was said to work out at 150 lb. of coal per head. In actual practice, however, extending over six months, it was found that not more than ten carcasses a day could be consumed, and that the cost of fuel was much larger than the original experiments suggested; on one occasion as much as twenty tons of coal being used to consume fifteen carcasses!

No more than two carcasses could be placed in the incinerator at one time, and they occupied about two hours for complete combustion. The kiln was erected on the reverberatory system; the heat from the fire hole ascended between two skins of brickwork, and was then drawn through the central flue to the chimney, the draught being regulated by an iron damper in the main flue. The carcasses were placed in the kiln by means of a crane. Experience in working showed that the inner skin of brickwork should have been made entirely of fire-bricks and much stouter, that the grating floor should have had larger holes so as to have allowed the charred bones to fall through; this would have prevented the clogging which occurred, necessitating the fire being allowed to go out in order to clear the interior.

The cost of erection and working, for the relatively small result obtained, appears to be prohibitive.

Where fuel is no difficulty and labour available, field cremation may be practiced by means of a cross trench dug in the ground, a detailed account of which method is given elsewhere.\*

#### DEMobilIZATION.

The termination of a campaign brings immediate relief to troops, but none to the technical branches of the army, and least of all to those charged with the duties of treating the sick and obliterating epidemic and epizootic diseases. The number of sick animals to be treated actually increases, as many which have been kept at work under pressure of military conditions are now available for repair, but, above all, the question of the obliteration of infectious and contagious diseases has to be taken seriously in hand. These facts are liable to be forgotten by the staff of the army, who, in a natural desire to reduce expenditure, press for reduction of establishment, and cannot understand why it is that a large veterinary staff is necessary after hostilities end. Hard as all previous professional work is, it now becomes still harder, for it is manifestly impossible to sell animals affected with contagious diseases, or those sick and lame. Some military and civil veterinary officers did not always realize why they could not be at once liberated from the country, for the rest which so many of them had both earned and needed. They did not, of course, know the extent to which contagious diseases existed, for in

a campaign all is darkness beyond the immediate visual field of those not in administrative charge. The Administrative Officer who parts with his staff before the slate is cleaned deserves the difficulties in which he will surely find himself.

On the day peace was declared there were 28,700 sick horses and mules to attend to, and an unknown number of sick oxen, certainly not less than 10,000. Glanders, mange, epizootic lymphangitis, specific ophthalmia, cattle plague and pleuropneumonia existed. All of these had to be dealt with and obliterated; the Army Veterinary Service had never previously to undertake such a gigantic task. These diseases were spread over a sub-continent, and, though the troops had concentrated on the cessation of hostilities, the affected animals were strung out on four long lines from the coast, narrowing to three as Pretoria and Mafeking, the two extreme northerly points, were approached.

The first anxiety of the military authorities was the reduction of the number of animals now surplus to requirements. On the day peace was declared there existed 131,700 army horses, 76,600 mules, 12,800 donkeys, and 74,200 oxen. The cost of keep of these represented an enormous daily expenditure, so that the almost feverish anxiety shown to dispose of the surplus numbers can be readily understood. A country left desolate by over two years of constant war is not in a position to purchase any commodity, let alone live stock for which no keep existed. This was the condition of affairs in the Transvaal and Free State, and for the regeneration of these colonies a department was formed with some millions of money at its disposal—provided by the conqueror—for the purpose of setting up the late enemy on his feet, and starting him on the road to recuperation. This Repatriation Department has already been referred to in dealing with the question of glanders (see p. 282 c.). It required animals of all classes, and, as we have already mentioned, needed them early and urgently, if famine was to be avoided. The Repatriation purchased from the military authorities:—

Horses	...	23,700
Mules	...	51,800
Donkeys	...	5,700
Oxen	...	60,900

This still left an enormous number of horses for sale in Cape Colony and Natal, where money and food existed, and some 86,800 horses, 9600 mules, 3400 donkeys, and 2000 oxen, were in this way disposed of before the end of February, 1903, to private individuals as apart from the Repatriation Department.

The total sales of equines between 1st June, 1902, and the 28th February, 1903, amounted to: horses, 120,500; mules, 61,400; donkeys, 9000; and this represents the amount of susceptible material which was spread broadcast over the country. We have already seen (p. 282 d.) that a mere trifle among these animals was malleined, and we also know the result of our utter inability to carry this out. No physical

\* See "A Manual of Veterinary Hygiene, 1905." F. Smith.

examination, no matter how conscientiously performed, can enable latent glanders to be detected without the mallein test. There were 9,500 horses and a similar number of mules destroyed between 1st June, 1902, and 28th February, 1903, and it is safe to say that at least one-third of this number was destroyed for glanders, so it is evident the disease was still rife. Nasal inspection was wholly insufficient to prevent affected animals being sold, and the consequent losses to private individuals, and especially the Repatriation Department, from glanders was extremely heavy.

Immense losses occurred from other causes, for instance: the majority of the horses purchased by the Repatriation Department were turned out on the late stock farms until required. No grazing existed, and no men were provided for the purpose of looking after the animals. How often has the lesson to be learned that horses cannot live without food?

Perhaps one explanation of the want of system in dealing with this stock was the difficulties which suddenly arose between the military and civil side. The "Times History" tells us\* that "weeks of desperate haggling" over prices occurred. The animals, and the food for them, were priced too highly according to the Repatriation view; in fact, the military supplies, of which enormous quantities were available for sale, were finally discarded on account of the high price asked, as the Repatriation Department found they could import food and feeding stuffs cheaper than they could buy it on the spot from the military! It passes all comprehension why two public bodies, supplied from the same purse, should have been permitted to "haggle" over prices; but it is authoritatively stated that the dispute went on for weeks, the military holding the stock and the Repatriation requiring it. Importations of food and stock from over-sea followed; one can understand when such desperate action as this was taken by the Repatriation Department, that the controversy left little time for considering the case of the 21,000 horses turned out on farms to shift for and look after themselves.

The above events led to disasters of the first magnitude, for the unsold military supplies deteriorated, and were finally disposed of under circumstances so scandalous that a Royal Commission was appointed to inquire into the matter.

We have seen the difficulty throughout the war in getting sufficient food for animals. On the day when peace was declared there were 100,000 tons of oats, and nearly double that quantity of hay in the various supply depots of South Africa.† Nor does the above represent all the supplies subsequently available for sale, as vast amounts continued to pour in until March, 1903. On 31st May, 1902, there was sufficient food in hand to have allowed every horse in the country 12 lb. of hay a day for eight months, and 12 lb. of corn for four months.

In the face of this it is extraordinary that horses should have been called upon to perform the most arduous and exhausting work on 10 lb. of oats, and no hay. This question, however, does not now arise. The food was available for sale for Repatriation animals, but, as we have seen, the two servants of the State failed to agree, owing to the "exorbitant terms"\* demanded by the seller, the result being that immense surplus stocks of food of all kinds, valued at £11,000,000, were left on their hands. Enforced sale now became necessary to save further deterioration, for all supplies were in the open, and we shall let the "Times History" tell the story † of "the most amazing blunders probably ever perpetrated":—

"A system was introduced of selling Government supplies to a contractor, who at the same time contracted to supply them back to the troops as they were wanted, at a difference in price which was supposed to allow a fair margin of profit after paying for sorting, removal, storing, issue and deterioration." The supplies, however, were not removed; they remained "where they were, and were served out by an A.S.C. subordinate as if nothing had ever happened, the only difference being that the contractor pocketed a heavy profit on the transaction."

To meet the army sales, mushroom contractors arose, and one of these secured within a fortnight contracts both to buy supplies and to supply them back to the army at a higher price. Oats sold at 11s. per 100 lb. were bought back at 17s. 11½d. "As the firm had no capital it was benevolently arranged that it should be paid promptly for what it sold, and given credit for what it bought. It even received a refund of £21,000 on goods for which it had not yet paid. Over this deal in oats and other goods the firm netted £69,000 without effort and without risk, and others made still larger profits." ‡ The loss to the State was estimated at between three-quarters to one and a quarter millions sterling.

The Repatriation Department met with other difficulties. They imported cattle, among other places, from Madagascar and German East Africa; with these they imported a new epizootic, the so-called East Coast Fever. There is reason to think that had the matter of re-stocking the country not been one of such urgency, greater attention would have been paid to the advice given to the civil Government as to quarantining these new importations at Lorenzo Marquez, the port of entry. They were not quarantined. In July, 1902, the newly-imported cattle were dying in large numbers at Komati Poort, and, under veterinary advice, it was recommended that the movements should cease, as they were suffering from "Rhodesian Red Water." Professional men, however, were far from unanimous as to the nature of this new disease; some declared

\* Vol. vi, p. 48.

† "Times History." Vol. vi.

\* Idem.

† Idem, p. 405.

‡ Idem, p. 615.

it to be Rinderpest, on the strength of the stomach and bowel lesions; some, "tsetse" disease; and amid these differences of opinion, which were perfectly natural on the introduction of a disease new to everyone, the civil side was urging the distribution of the cattle. They were allowed through, or at any rate came through, by rail and by road. They infected the Transvaal as far north as Pietersburg, to the west as far as Rustenburg, and the whole length of the road Komati Poort—Pretoria. In a few weeks the damage revealed itself, and from that long line the disease spread south, through Natal and the Free State. We are writing of events which occurred twelve years ago, but that period has not been long enough to obliterate East Coast Fever. It has brought ruin in its train, and cost countless thousands of pounds to South Africa.

The above does not complete the account of the curses attending war. The War Office, knowing the large surplus of animals in South Africa, saw no objection to bringing home horses from a country gravely infected with disease. They acted without veterinary advice. Every care was taken in the selection and inspection of the 800 required, and nothing was put on board to which a shadow of suspicion attached. The animals were selected from several centres, so that the risk of picking up something on the way to the port of embarkation had not suggested itself. On the arrival home of the ships hundreds of animals were found affected with mange. This was bad enough, but worse was to follow. The apparently unaffected horses were issued to batteries in various parts of the United Kingdom; among these animals epizootic lymphangitis appeared, and through sales of cast animals, this disease eventually spread to the horses of the civil population.

By this time surely the cup had been drained to the dregs! Everything that could possibly happen took place; every blunder that could be made was perpetrated. The Government knew for a year prior to the ending of the war that there was a feeling against bringing horses home from South Africa, mainly on the score of expense, and Lord Stanley, on 7th June, 1901, said there was no intention of bringing home the horses which had been sent out;\* yet, a year later, this was done, and without consulting professional opinion as to the wisdom of such a policy.

The horses arrived home in August, 1902; it was not until December, 1903, that M'Fadyean recorded a case of Epizootic Lymphangitis in a horse attending the clinique of the London School. The animal was a cast horse from the service, and bore the brand of having been in South Africa. At this time the disease already existed in several military centres; five months later, May, 1904, other cases of the disease were met with in civil life, though confined to cast horses, and the Board of Agriculture published an "Epizootic Lymphangitis Order"

preventing the movement, and securing the isolation of animals so affected. By July, 1904, the question assumed so alarming an aspect that information was asked for in the House of Commons. The Secretary of State for War stated that the total number of army horses affected to date was 394, and that the disease existed at 30 different military stations, the worst being Woolwich, where 231 cases had occurred; 254 in all had been destroyed, 32 recovered, and 108 remained under treatment. All sales of cast horses from affected units were prohibited for six months after the last case of the disease. A year later, April, 1905, it was elicited in the House that of the above 108 cases remaining in 1904 sixty had been destroyed, and that 96 fresh cases had occurred during the year in English garrisons, one in Scotland, and five in Ireland. On 12th May, 1905, the Secretary of State informed the House that the disease in the army had practically been stamped out.

The above summary of a serious and costly outbreak of disease, and the introduction of a new terror to horse owners in this country, was entirely due to the neglect to take veterinary advice. No one with any notion of the extent to which the horses in South Africa were exposed to infection, in an army literally riddled by epizootic diseases, would ever have thought of carrying this combustible material to a clean country. Who was to blame for this waste of public money? The question was not publicly asked, but there is little reason to doubt that the suggestion to bring these horses home arose with the Remount Department of the War Office, or at any rate, received their approval. It was the culminating blot on an Administration which from first to last blundered through ignorance, not only in its own special work, for which no ignorance is excusable, but in all veterinary matters with which it interfered. The evidence on these points has been fully set forth in the previous pages of this history.

The remaining act of demobilization was concerned with the personnel. India had for two and a half years been kept short of its proper proportion of veterinary officers in order to supplement the numerical weakness in South Africa. Seventeen officers were returned to India before the end of 1902. Fifty Civil Veterinary Surgeons were also sent home or took their discharge in the country on reduction of Establishment. The whole of the Indian Hospitals, together with their personnel, were returned to India.

By December, 1902, the fifty Field Veterinary Hospitals had been disbanded; twelve Station Veterinary Hospitals were formed for the Army of Occupation, and four Mobile Hospitals organized. The stores in the various advanced Depots were distributed among the Station Hospitals, so that each should possess an independent reserve in the event of difficulties arising. The base depot at Cape Town was retained, and into it all material surplus to the above requirements was returned.

\* See *Times Report*, 6th and 7th June, 1901.

*VETERINARY STORES AND EQUIPMENT.*

A consideration of this subject mainly resolves itself into questions of supply and distribution. The early history of both these have been incidentally dealt with at p. 4, where it has been shown that the army, presumably ready to take the Field, was without veterinary equipment of any kind, excepting a few old chests of the Peninsular and Crimean days. It is almost beyond belief that such a state of affairs existed, but it had its parallel in the astonishing shortage of all other military stores and equipment, to which sufficient reference has already been made at p. 3. As a matter of fact, the Force did not take the Field without equipment: owing to the steps taken by Colonel Duck, the then Director-General (see p. 9), sufficient material had been constructed to furnish each unit with an outfit, but it was the bare minimum, and not calculated to last more than three months. A reserve of this equipment for meeting wear and tear did not exist; the measures for replenishment were of a meagre and hand-to-mouth order, and only included a few of the more common drugs, and no instruments. For hospital equipment nothing existed but a few pairs of obsolete panniers; this cannot be wondered at, as hospitals formed no part of the War Office scheme.\* The supply of stores to an army in the field is carried out by a depot under an officer with a staff of subordinates. The officer is responsible for the receipt and issue of stores, the record of which is made in ledgers and supported by receipts. It was known that a Veterinary Store Depot would be required, with a properly trained technical staff of ledger keepers, store-holders, issuers, packers, men for the purpose of off-loading and loading the various means of transport conveyance, and a building for the reception of stores and the transaction of business. Nothing existed. No officers had been trained in the technicalities of store management, no storehouse existed, and not a single subordinate of any kind. The measures taken by Colonel Rayment at Cape Town, and Major Crawford at Pietermaritzburg, to remedy this state of affairs have been recorded at pp. 10-13. The Authorities were not ignorant of these requirements. We have seen, at p. 113c, that the only scheme approved by the military department for the supply of stores in the Field was a base depot under an officer, and an advance depot under a Farrier-Serjeant! To this man, under no skilled supervision, was to be entrusted the responsibility of issuing poisons and suitable dressings to the army. The whole thing was incomprehensible; nothing, of course, came of it, for neither the man nor the depot existed excepting on paper. The scheme was too wild to admit of consideration, nevertheless, it is necessary to draw attention to the matter as one explanation of the shortcomings of a branch of supply which had to be created in the

Field out of nothing, and, throughout, worked under the greatest stress and difficulties.

The entire absence of any reserve of drugs, dressings or instruments was due to the parsimonious policy of the Cabinet. The impression existed that when material was required it could be bought from the trade. That the prices would then be famine prices was not considered as a deterrent, and the fact that even wholesale houses have a limit in their capacity for delivery was not taken into account. Worse than all, it never seems to have entered the minds of the economists, that the stock of instruments held by the largest houses is only sufficient to meet the ordinary trade, and that if this material were required in large amounts it would actually have to be manufactured. This turned out to be the point on which the whole of the delay in supply worked. Taking the Field without a reserve meant serious delay in supply, for the whole of the material had to be produced, and it was never possible to overtake this initial delay. This was the explanation of the natural grumbling which existed when veterinary officers were unable to obtain for their large hospitals the full amount of dressings and instruments asked for. Those which existed in store had to be doled out equally all round, and the supply never could keep pace with the demand. Another result of this panic form of supply was that material defective in manufacture was received; thermometers incorrectly graduated, hypodermic syringes marked in cubic centimetres instead of minims, and even then of wrong capacity and unequal bore, steel goods of brittle manufacture due to haste in tempering, these and a series of other defects led to increased strain in the matter of supply. It took four months from the time a cable was despatched before stores were received in South Africa. This speaks for itself, and try as one would to anticipate requirements it was impossible to obtain the mastery. Every month saw thousands of horses pouring into the country, all of which, as we have seen, only added to the large number already sick and inefficient, for which drugs, dressings and instruments were required in ever-increasing quantity.

The cost of veterinary stores during the war ran into some hundreds of thousands of pounds, yet not a single officer was exclusively available for the care and distribution of this public property. It was added to the duty of a man whose hands were already full, and who could only devote a fraction of his time to what should have been an entire charge. This officer had to train himself in the intricacies of military supply and accounting; no previous training in this essential duty had been given the officers of the A.V.D., apparently it had never been thought of. The comfortable peace system of getting all that was required direct from wholesale druggists and instrument makers did not lend itself to the training of officers in a duty of the utmost moment on taking the Field, and, in consequence, no scheme had been thought out and no instructions issued.

\* See this History. pp. 3a, 5d, 10a, 63a, 113b, 114a.

Everything was left to the usual policy of drift, in the hope that the stress would never come, or that if it did we would muddle through. For this state of affairs only those are to be blamed who denied to the army the stores it required, and reserves of the same. No training of officers in supply could take place if the material for training them did not exist. If the officers were untrained and the subordinates did not exist, no great effort of imagination is required to form a picture of the confusion, delay and want of system which at first occurred, when establishments for the supply of veterinary stores had to be formed at Cape Town in the middle of hostilities.

While material was being obtained from home for the formation of these store depots, every principal town in Cape Colony and Natal was being ransacked for drugs and dressings. Instruments, of course, were impossible to obtain. Contracts were given to a firm in Cape Town to build Veterinary Field Chests at double the price which would have been paid for the same article in London, and the ships arriving with troops and remounts brought with them medicines surplus to the ships' requirements, which were as far as possible collected and issued. This source was not only irregular but very one-sided, for the material remaining over at the end of the voyage was mainly that which was not needed, for instance, powdered gentian and mustard, of which in due course some tons were received. These no one in the Field required any more than they had been needed at sea. Of the important medicines the balance handed over by ships was relatively small, but nevertheless helped out the question of supply pending the arrival of stores from England. The requisitions on England for the first fifteen months of the war were always based on the supposition that the war might end any day; in the meantime not only was the end of the war as far off as ever, but the number of horses in the Field had increased considerably. This state of affairs lasted throughout the war; it is almost unbelievable that those responsible for maintaining the supply of veterinary stores in the Field were never informed of the increased number of horses which had been called for. Estimates would be framed on one number, while in the meantime thousands more horses and mules had been added to the establishment.

When hostilities broke out the centre of military interest lay in Natal, it was accordingly on the base at Maritzburg that the first pressure of the war fell. Throughout the campaign Natal retained its Depot, as owing to the distance from Cape Town the supply of material to the troops in that colony was greatly facilitated. When the centre of military interest shifted into Cape Colony the struggling Cape Town depot began to feel the stress, but in spite of this Colonel Rayment organized an advanced depot in the heart of hostilities at Naauwpoort, and thereby met all the requisitions on the spot, thus saving a week or two's delay in obtaining the material from Cape Town. There

was no staff for this advanced depot. It had to be tacked on to the Veterinary Hospital, and looked after by the officer in charge as an additional duty (see p. 20b). This depot moved forward when Bloemfontein was occupied, and rendered service of the greatest importance at a most critical time (see p. 58d). The inception of these advanced depots was entirely due to the organising capabilities of Lieut.-Colonel Rayment then acting as P.V.O. In due course another depot was opened at Kroonstad for the supply of troops in its vicinity; later at Pretoria, and in fact, as the line of communication became extended, and veterinary hospitals established, veterinary store depots were formed in connection with these under the same officer, but in all other respects distinct.

A glance at the map shows how unfavourably Cape Town was situated as a base relative to the seat of war. There was a railway journey of 600 miles before the area of hostilities was reached; to remedy this and expedite delivery of stores to the troops, it was decided in January, 1901, to remove half of the Cape Town base to De Aar. At this latter place a large Depot was formed in connection with the Hospital, which supplied all the subsidiary depots in the area of hostilities not supplied by Natal. The result was an enormous saving in time. The depots at De Aar and Pietermaritzburg were kept filled up from Cape Town. The system of supply was, therefore, a base depot supplying advanced depots favourably placed in the field, which, in turn, supplied subsidiary depots in the centre of hostilities. Such a system gets at the root of matters and if, as was aimed at, a three months' supply could be maintained at these various depots, the supply for the troops was independent for some time of delays on, and destruction of the line.

The only veterinary equipment carried with troops in the Field was the new universal pattern chest, already spoken of at p. 4, and the veterinary wallet. The latter was carried on the saddle by farriers, the former was conveyed with the squadron or battery stores, and could only be got at in bivouac. This was obviously wrong, for apart from the damage done to these chests by being thrown into heavily laden waggons, they could not be got at in an emergency, so that veterinary officers had to carry on them not only their instruments, but first aid dressings and medicines for emergency.\* The result of there being no special conveyance for veterinary stores with the troops led to destruction of these chests, which were lightly constructed. The run on them was accordingly very great and could never be kept properly met, in spite of supplies from home, from local manufacture, and by drawing on reserves belonging to the Government of India. We may look a little more closely at these chests; they were the outcome of Colonel Duck's experience in India, and aimed at giving

\* In the guerilla war Columns employed a Cape cart for the carriage of Veterinary stores, in this way material was always available.

a supply of drugs, dressings and instruments calculated to last a unit for three months in the Field. The weight was 80 lbs. These U.P.\* chests, as they were briefly designated, were excellent for the personal use of Veterinary Officers, but too elaborate for those units with no officer attached. They cost in London £20 apiece, and took on an average four months to manufacture. It is obvious that they could only contain a selection of drugs, and even these in small amounts. The principle on which the drugs and dressings were to be replenished was by means of Reserve Boxes containing packets of drugs, and dressings, of sizes suitable for the chests. For a brief campaign such a system would work quite well, the reserve boxes being held at an advanced depot. It was not anticipated that either instruments or fittings would require to be replaced. For completeness and portability these chests could hardly be improved upon; the only difficulty was to find in a hurry what was required, or to repack in haste; there were no spare places, every inch of room was utilized.

It was soon found that these chests in the hands of laymen were stripped of their contents; the instruments, especially knives and scissors, and useful fittings, such as flasks, disappeared, and the chests were returned to the depot practically as an empty shell, needing not only drugs, dressings and instruments, but fittings, such as trays, canisters, etc. These chests, as stated above, were too good for use with any unit where no veterinary officer was present to ensure their being treated with consideration and ordinary care. Some 1300 of them were issued during the war, and many were refitted over and over again. At the end of the campaign hundreds were useless owing to destruction and deterioration, and little but the outside case survived.

The veterinary wallet carried on the saddle by farriers for first aid purposes was a useful accessory, but there had been no time to bring it up to date before the war. Some 850 were issued during the campaign, and had they been more modern in the matter of contents they would have met all the calls made on them in the Field.

Hospital equipment was represented on the outbreak of hostilities by a few pairs of panniers, very heavy, and obsolete in character. As we have seen, at p. 10, until something more modern could be manufactured, the Government of India was requested to furnish hospital equipment.

The supply of reserve drugs and dressings was intended to be met by the Reserve Boxes above described, plus the material remaining over in horse transports, but it soon became evident that this source would be wholly insufficient, and local purchases, both in the Cape and Natal, were required in an endeavour to meet the ever-growing demand. The bills in Cape Town alone ran into several hundreds of pounds a month, and in course of time,

and the continuation of the war, it was evident that this was a very expensive source of supply. In December, 1900, matters were placed on another footing, and an attempt made to obtain everything from home by cable, but this opened further complications in the matter of personnel for stores. Prior to the above date it had not been found possible to obtain the needful ledger-keepers or store-holders, and practically no record of receipts and issues had been made. A Farrier-Sergeant of Cavalry, under the supervision of an officer, was issuer, packer and general utility man, with a small staff to assist him. A Sergeant of Infantry collected stores from the horse-ships and despatched orders up country, but anything more than this could not be attempted. With the supply of stores from home the previous hand to mouth policy, it was hoped, would cease. A four months' stock at the base was projected, and all receipts and issues were in future to be recorded. It may be explained that the War Office system of accounting requires that every separate item shall have a folio in the ledger devoted to it, showing on one side the receipts, on the other the issues, both being supported by receipts. There is as much clerical work involved in issuing a dozen corks as there is in issuing a ton of magnesium sulphate. Where was the trained staff to come from for the refinements of a business house? Civilians in abundance existed at Cape Town, refugees from Johannesburg, waiting for the war to end to resume their occupations, but they were ignorant of the niceties of military ledger keeping, in fact guileless of book-keeping in any form. They were starving and glad of employment, but the material for starting a new departure was hopeless, and as the engagement was only from month to month they took no interest in the work. This point is briefly referred to in the narrative in order to explain the difficulties which occurred later on.

The nature of the demands made on Home in order to attempt to keep up the supply in South Africa beggars description. Medicines were ordered in hundredweights, several of them in tons; there was a standing order, for example, for 10,000 gallons of linseed oil monthly, and, during Rinderpest time, of 800 lbs. of glycerine monthly; vaseline and lard were ordered by the ton, scissors by hundreds of pairs, syringes the same, bandage material by thousands of yards, yet we were never able to overtake demands owing to the initial failure caused by an entire absence of reserve, and the subsequent delay in supply. Even when the material arrived at Cape Town, owing to the congested condition of the docks, the ship would lie from one to three weeks in Table Bay awaiting her turn to discharge, and in the meantime orders were increasing in urgency, and the whole stock would be issued within a few days of its receipt. It is obvious that an equable distribution had to be made; there were fifty hospitals at work, exclusive of demands made by the troops, and the supply received from over-sea had to be doled out in the proportion of

\* Universal Pattern.

the number of sick these contained, holding a minimum of reserve in hand to tide over difficulties until the next supply came to hand weeks hence. It is hardly a matter for surprise that veterinary officers complained of the difficulties and delay in the supply of stores. Their requisitions were not always framed on an economical scale; they were anxious to maintain a reserve, knowing the great delay before the next issue, of instruments especially, could be made, but as we have seen, the stock did not admit of a reserve of all surgical appliances, though to a large extent it did of medical.<sup>o</sup>

Veterinary officers with units in the Field also complained. They would ask for stores to be sent to a certain point by a given date: the time was often insufficient, for the trains were allotted for the various supplies according to the pressure of circumstances, food always having the prior claim, and veterinary stores the last. Trains also were blown up and burned; or material would be removed from them *en route* to make way for something more pressing, and the removed stores were perhaps never heard of again, or were found months afterwards in a railway store. Again, columns pointing on a certain objective by a given date, were, as we have seen, frequently diverted owing to sudden military necessity; their stores arrived but they were not there to receive them. The above reasons by no means exhaust all those which could be offered in extenuation of delay or non-receipt of supply, † they are only mentioned as evidence of the difficulties over long lines of communication in getting material to its destination, and prove the necessity for many subsidiary depots in the Field from which issues to the troops may be made direct.

A considerable amount of useful information was acquired concerning the methods of sending stores into the Field, which may here be recorded for future use:—

(a) Boxes must not be too large; the labour for handling heavy goods does not exist once the stores leave the ship; it is easier also to find store accommodation for cases of moderate size.

(b) The contents of each case, chest, barrel, drum, etc., must be specified outside; without this information case after case has to be opened to find something urgently required. Taking as an example, 71 cases, 108 drums, and 45 kegs, an actual month's supply, it meant if a certain box of instruments or appliance were urgently required, case after

case had to be unnecessarily opened in order to find it, and their contents mislaid before being checked. Drums containing oil are only marked with difficulty, paint does not dry: the only system is a stamped metal label showing contents and weight. Barrels should never be employed for the carriage of stores if they can be avoided; they are wasteful in the matter of storage, very liable to breakage if light, and far too heavy if strong. Vaseline and lard were sent out in large barrels; the contents were rendered semi-fluid in the tropics and escaped through the staves.

(c) Lard, soft soap and vaseline should be in 10 lb. tins, nothing larger; in this way waste is avoided on issue, for the tin is sent out as received, soldered and intact. Similarly, all drugs should be put up in packets of a convenient size, ready for issue; for instance, a demand on Home for half-a-ton of Boracic Acid or Magnesium Sulphate should not be met by sending it in bulk in kegs, but as 1120 one-pound packets, ready for issue. No weighing-out or tying-up should be required at the base, and nothing less than a packet issued.

(d) Large packets of surgical dressings are most wasteful; ounce packets are not only conveniently carried, but if opened and not used up, the soiling and deterioration is less.

(e) Whenever tins can be used they should be employed, but there are many articles which will not travel in tin: Burgundy Pitch, for instance, eats its way through in a very short time; some preparations of Soda and Tincture of Cardamons also act on tin.

(f) Balls of all kinds deteriorate; Aloetic balls are useless after a few months, and those of Ammonium Carbonate after a few weeks. They should be in dozens or half-dozens in a soldered case.

(g) Ether and Chloroform escape even though carefully secured stoppers be used; some special luting is necessary.

(h) Glass stoppers, corks and bungs, packing paper and string are required in large quantities, stencil plates for addresses, carpenters' and cutlers' tools.

(i) A base store depot requires a general utility carpenter, also a cutler who can repair as well as sharpen instruments, including clippers.

There are certain stores which would be better if drawn from some other department of the army rather than the veterinary. Linseed oil, soap and clippers are required everywhere in such immense quantities that they should be an Army Service Corps and Ordnance Supply. This would ensure that they were always obtainable, for wherever a Supply and Ordnance Depot existed, there oil, soap and clippers would be found. Both of these departments have naturally far greater facilities afforded them for transport by rail and road than that allowed to the veterinary service, whose stores were, as we have stated, frequently off-loaded on the road to make room for something regarded as more pressing. So much was this the case that

\* An example of a few items required by an advanced store depot, may be taken as a fair example of the stock which had to be held in order to meet requirements. This one requisition demanded among many other articles:—

Lard	...	...	2000 lbs.
Lard Oil	...	...	2000 galls.
Bandages	...	...	500 dozen
Four different Oils	each	...	100 galls.
Glycerine	...	...	100 galls.
Silver Nitrate	...	...	5 lb.

and other articles in proportion.

† Of eight U.P. chests sent at various times to an officer, not one ever reached him.

it was repeatedly found necessary to send urgently required stores by hand, or under supervision.

The control of the Base Stores at Cape Town should have been the work of a specially selected officer, but no one was available, and it fell to the veterinary officer at the Base (see p. 48) whose hands were already full with his own duties, and finally on the Senior Veterinary Officer of the Cape Colony Command. The P.V.O. had no officer he could spare to take over what was an immense business concern, although, as we have seen at p. 194c, Colonel Long had an executive veterinary officer travelling about with him.\* The entire responsibility of this huge work fell on a man whose hands were already full, and whose duty lay over some thousands of miles of communication. The subordinate staff supplied him we have already glanced at, and its makeshift character—untrained men with no knowledge of the work in any of its branches, ignorant of the complexities of issuing and accounting for army stores; a soldier personnel which, having learned something of the rudiments of the work, were suddenly taken away to rejoin their regiments. The illness of a store holder or packer brought matters to a standstill, for in the confined building supplied, stores stood several feet in height, and only the man handling them knew where things could be found. Officers were sent from time to time to render assistance, but all but one were invalids and soon went sick; yet the work had to go on, requirements months in advance had to be anticipated, and the pulse of the entire mechanism constantly felt, in order that the work of supply should be regular, and the distribution of drugs, and especially instruments, equable. A regular study of demand and stock was required of the hundreds of medical and surgical articles in use, while the ledgers had to be inspected to see that they were posted, and incessant calls for outstanding receipts made.

Hitherto the story of the stores has been that of supply and distribution, but it is not possible to conclude the subject without recording the inquisitorial inquiry which followed the termination of hostilities. When the end came civilians from the War Office arrived armed with lists of all stores sent to Africa; they began operations by taking stock of what remained, and then asked for a full explanation of all issues made during the past two-and-a-half years of pressure, supported by receipts! For three months the Senior Veterinary Officer was engaged with these courteous but inexorable officials, endeavouring to explain, in the absence of receipts, how and in what way hundreds of tons of stores had been disposed of. It may be judged from the previous remarks that the issue of a suture needle gives as much clerical work and correspondence as a large case of instruments, or an aloetic ball as much as 10 lb. of Iodoform. We also know from the narrative that for the first fifteen months of the

war no receipts or record of issues had been kept, but that the whole energies of the staff had been directed towards keeping the army supplied under extraordinary difficulties, instead of concentrating on ledgers and receipts for which there was no clerical staff.

One would have thought these gentlemen had never heard of war pressure and confusion, had never read of the destruction of trains and convoys, of the loss of stores in the Field from preventable and non-preventable causes; of the chaos and confusion resulting from unexpected military conditions, nor of the unrelenting, unyielding dead pressure of two-and-a-half years' campaigning. They took the academic view that a supply must be entered on one side of a ledger, and expended on the other, a receipt covering every issue. As to whether the circumstances of the case permitted, or the available mechanism existed, for carrying out in war the refinement of a place of business in peace was no concern of theirs. Two points strike the observer in connection with this inquiry: (1) That it could lead to nothing; it could not recover stores burned in trains, lost in rivers, or abandoned on the veldt; it could be of no use to those who required the stores and did not receive them, nor to those who received and made the best use of them. (2) It did not demand compensation from those units who carelessly treated and damaged stores, or allowed the contents to be pilfered. Curiously enough it did not appear to strike the academic mind that the sole effect of their inquisition was to worry unnecessarily the only persons who had a claim on their consideration, and took no account of those whose business had been to expend it. In other words, it could not lead to any economies, for so long as a receipt could be produced it was no concern of these gentlemen whether the issues to any one unit were twenty times in excess of what corresponding units required, nor what was done with the material when so received.

For three months this solemn farce of audit went on; sheets of queries often arising, as an examination of the ledgers revealed such discrepancies, for example, as the following, taken from actual remarks: "Under date . . . 4000 flannel bandages are entered in the ledger as 3826. Explain the discrepancy?" Here is another; "20 cwt. 3 qr. 9 lb. vaseline brought on charge as 20 cwt. only. What has become of the balance?"

The horse-ships were a favourite subject of attack. The unexpended drugs on these were as far as possible collected, and supposed to be brought on ledger charge. There were 520 voyages made by horse-transports during the campaign, and each of these vessels should have appeared in the ledger as landing drugs. Some landed them, some did not. They were frequently forgotten by the Transport Veterinary Surgeon; small wonder, when it is borne in mind that owing to the congested state of the docks the last horse was hardly across the gangway when the ship was moved off to make-way for the next. Even if the material were landed

\* A C.V.S., also, was uselessly sent to Australia (see p. 225c).

it could not always be recovered in the bustle of clearing the quay for the next vessel. The War Office Auditors finally submitted a list of 70 horse ships, in which they ask for information regarding the balance of medicines existing on vessels which arrived two years previously! Five minutes spent at the docks during the war would have been a useful object lesson.

We do not propose to extend the criticism of this audit any further: sufficient to say that the supply of an army in the field for a long campaign was an easier task than three months with the War Office Auditors. It is doubtful, even had they been on the spot during the war, whether it would have led to any practically useful results, for, after all, they did not look for efficiency in supply, but merely ledger records. As an example of academic finance the following may be recorded:—

The officials who made the above inquiry were requested to sanction the issue to the troops as firewood, of some 300 U.P. chests returned after the campaign and unfit for further use. Firewood had to be purchased for the troops, and was scarce, so that a saving would have resulted. They decided, however, that the chests must be sold by public auction. The auctioneer's fees and advertising came to over three pounds, the articles were sold for 7/6, and the man who bought them left them on the ground after removing the copper enema tubing. The chests had finally to be burned where they lay.

While the rigorous financial scrutiny of veterinary stores was being carried out at Cape Town, the financial blunders connected with the sale of food-stuffs, recorded at p. 298c, were being perpetrated. These were the outcome of the absence of a financial adviser. Had the gentlemen who were employed for three months dealing with petty questions of veterinary stores, gone beyond recovery, been engaged with matters of immediate interest and practical importance, they would have saved from three-quarters to one-and-a-quarter million sterling to the country.

#### VETERINARY SERVICES.

The last question we have to deal with is that of the Veterinary Services employed during the war and their organization. We have used the plural intentionally; there was not—as there should have been—a single veterinary service under a central administration, welded into one compact whole and discharging its military duties under skilled direction. This fact will have been already gathered from these pages, but the point needs emphasis, both in explanation of our numerical weakness, our shortcomings, as well as our inability to obtain the best results from the material on the spot. What actually existed was a series of veterinary services, each independent of the other, and only one of which possessed a directing or administrative staff acting under central control. The others possessed

no organization, were independent of everyone excepting the commanding officer of the regiment, and their strength was frittered away for want of organization and unity. The following constituted the veterinary services employed during the war:—

- (1) Officers of the Regular Service
- (2) " " Imperial Yeomanry
- (3) " " Over-sea Colonial Forces
- (4) " " South African " "
- (5) Civil Veterinary Surgeons with the Field Army
- (6) Civil Veterinary Surgeons with the Sea-Transport Service

Groups (1) and (5) worked together; groups (2), (3) and (4) were independent, without administrative officers, and under no departmental control. As a consequence their strength, which was very material, was entirely lost to the army at large; practically they went where they liked, and did what they liked; excepting as volunteers, they could not be employed on any duty other than with their regiments. No other departmental branch of the army was similarly handicapped; in no other branch were there officers actually on the spot who could not be utilized for general duty, and for whom no administrative staff was provided; no other branch had to cable to England for further professional help at a time when it was at hand, but could not be employed. The story seems incredible, but so ignorant are we of groups (2), (3) and (4) that even at the present day the number and names of the officers employed are partly or wholly unknown.\* For this condition of affairs the authorities who sanctioned a regimental organization for the veterinary services of the irregular forces are alone to blame. They knew that in the regular service it had been tried for a century, and, though capable of working in peace, it had at once broken down in war. (See p. 5b). Their approval of an obsolete and effete system for the irregular forces showed not only a lack of knowledge of the subject, but also a want of appreciation of the difficulties of untrained men in dealing with sick animals in war. It also showed a complete ignorance of the value and utility of administrative veterinary officers in the Field.

To send a body of technical officers on service without a directing head, is like sending troops into action without officers. Without administrative heads responsible for the proper working of the veterinary service the executive officers are literally as sheep without a shepherd: this condition is naturally accentuated by the ignorance of military matters of officers of the irregular services. Each in his own way, and according to his light, was doing his best, but individual efforts may fall far short of what is necessary. It is impossible where the executive is ignorant of military methods and of war, that they can anticipate the unknown or provide against contingencies of which they have never heard. Their efforts should have been co-

\* As a consequence we are compelled to forego the list of names promised in the footnote on p. 20a.

ordinated by an administrative service, a general policy given them to follow, a driving mechanism furnished to keep the current flowing, and a responsible person to direct and advise young officers on technical or military questions at a time when such advice and help is all-important. It seems beyond belief that this body of voluntary professional helpers was thrown into the Field and left to work out their own salvation. It was an unfortunate waste of useful material for which the authorities must be held responsible, they having, as we have seen, sanctioned the system for the veterinary service of the Imperial Yeomanry at a time when they had abolished it from the Regular Forces on account of its uselessness.

The difficulties and disadvantages of which we speak were those personal to the officer, but these by no means cover the question. It must have been known that the horses of the Irregular Forces would suffer from accident and disease, and, as a fact, we knew that the Yeomanry had visions of a veterinary hospital as part of their scheme. How was it supposed that the disposal of the sick in the Field, or the organization of hospitals for their reception were to be effected by officers with no knowledge of either question, or of military service? We shall see presently the Yeomanry effort to establish a veterinary hospital and its results. The criticism directed by the Yeomanry Authorities against their veterinary officer for his failure in this respect is obviously unjust, and shows a profound ignorance of the technical difficulties concerned. We are not born into the world with knowledge; everything has to be acquired by training and experience. In the case of the Yeomanry and other Irregular Forces there were no administrative veterinary officers, and consequently no senior officer to whom they could look for technical advice, guidance or inspiration.

We may now take each of the units comprising the Veterinary Services during the war, and glance at their work.

#### ARMY VETERINARY DEPARTMENT.

When war broke out the strength of this department was fifty officers short of requirements for the Field, and there was no reserve.\* By keeping the meagre veterinary establishment of India short of ten officers, a total of sixty-one was obtained for the campaign, and this left no one in England but the War Office and Educational Staffs. It was evident that not only were the available numbers wholly insufficient for the needs of the Field Army (see pp. 4c and 30c), but also that not a single reserve existed to make good the wear and tear of war. The veterinary officers of the Irregular Forces instead of being put in the pool were, as we have seen, kept distinct, and in order to supply the extra numbers required a Civil Veterinary Service had to be created as an adjunct to the Regular Service.

The growth and training of the Veterinary Service

are referred to at pp. 5b, 28a, 73d and 117a, and need not be repeated. An army is a vast educational machine engaged in the training of men who are joining or leaving it every day. The officers are the schoolmasters, and their work, in turn, is supervised by higher authority. In the various departments of the army the officers are broadly grouped into executive and administrative; the executive officers correspond to the schoolmasters in the fighting branches, the administrative are obviously the supervisors and directors. There is a somewhat irregular standard of proportion of administrative to executive officers, which we need not enter into, but it is evident that, during war, an expansion not only of executive but of administrative officers is required. The administrative officer is charged not only with the supervision in every respect of the executive, but on his shoulders falls, as the technical representative of the General under whom he serves, the responsibility of making provision for the sick, stamping out or controlling epizootic diseases, questions of dieting, of suitable or unsuitable feeding stuffs, and of making recommendations for the better care of animals and their preservation from accident and disease. In a word—he is responsible for everything connected with his officers and their subordinates, for the health of army animals, and the proper provision for their care and treatment when sick.

On the energy and ability of the administrative staff hangs the fate of the service they represent. As a consequence, they cannot be selected with too great judgment. Full professional endowment combined with seniority do not make an administrative officer, any more than they make a commanding officer of a regiment. There must be in addition an innate capacity for the work of organization and dealing with men, grafted on a constitution of physical fitness, activity, and relative youth. The administrative officer must ever be the highest example of devotion to duty which can be placed before his juniors. His place is not in an office, but among the troops; he must be on the spot, seeing matters with his own eyes, seeing his officers at work, helping them out of their difficulties, solving their doubts, assisting with advice, stimulating zeal, and bringing to notice exceptional ability. He should encourage initiative, for this is the means adopted by the capable individual to carry out the plans and aims of his administrative officer. These aims should be known to all his subordinates, for without such knowledge not only are they working in the dark, but may actually, through ignorance, frustrate his plans. The water-tight compartment system adopted by some is absolutely senseless. Reticence is imposed on administrative officers in regard to certain well-understood questions, but to carry this to the extent of not allowing the right hand to know what the left is doing is a misconception of office, and will surely bring its own punishment. His officers must clearly under-

\* The peace establishment is given at p. 4c.

stand the scheme he wishes followed for the inspection and treatment of the sick in the Field, the early detection of contagious and infectious diseases, the methods of dealing with large bodies of sick and debilitated animals, the management of Field Hospitals, the principles and practice of evacuation to Stationary Hospitals on the line of communications, the supply and distribution of medical and surgical stores, in fact, everything connected with the relief of suffering and early restoration to usefulness.

The number of administrative officers in the Field obviously depends upon the strength of the Force employed. But it is clear that where the bulk of the executive is civilian, as in the war under consideration, a further increase in the number of administrative officers is necessary in order to cope with the want of training of the civilian staff. As a matter of fact there were, at any period of the war, fewer administrative officers in South Africa than were sanctioned for home during peace time. For the first five months of the war there were nominally two, but as one was shut up in Ladysmith, there was actually only one administrative officer for the whole of Cape Colony and Natal, with four bases, four lines of communication, and an immense number of animals, for the veterinary care of which he was nominally responsible. We have already studied in detail what occurred during this crucial period in the matter of the wear and tear of animals, and the hopeless position of the veterinary service, with no hospitals for the sick and no administrative officer in the Field to organise and direct the veterinary work.

Even had both the above officers been available, it was impossible for such a microscopic staff to control the immense area of operations which daily became wider and longer. To realize these distances we may conveniently refer to the comparisons made at p. 6d. It is easy to understand the veterinary chaos occurring as the result of there being no guiding hand on the spot, the only place, as we have seen above, where the administrative officer can effectively perform his duties. Each line of communication, each base, each Division of the Army, the Cavalry Division, the Mounted Infantry organization, and the Transport needs its own administrative officer. All the faults in the veterinary service pointed out in these pages were accentuated by the absence in sufficient number of directing organizing heads of ripe experience and sound judgement. Even the errors arising from the employment of an untrained civilian staff would have been materially corrected by having senior officers present for its guidance and instruction.

Every representation to create temporary administrative appointments with local rank met with a refusal on the part of the authorities, yet, as we have already mentioned (p. 49d), every other branch of the army had temporary rank granted to officers acting in a higher capacity. Excluding the P.V.O., who, as we have seen, was not available until the

war was five months old, some eight or nine administrative officers were required for the first phase of the war. Can it be wondered at that in the Field there was an entire absence of cohesion in the veterinary service, with not a single officer empowered to hold it together or work it? Can it be a matter of surprise that the service failed when it possessed neither directing heads nor appliances to work with? Later in the war there should have been at least twelve administrative veterinary officers in the Field, including those required for Hospital purposes. Had these existed, no occasion for the appointment of a layman as an Inspector of Hospitals would ever have arisen.

We have devoted some little space to explaining the duties of administrative veterinary officers in the Field, as they are not generally understood; even the Staff did not appreciate their utility or necessity, though glad enough for help when the technicalities of the work became too much for them. No body of workers, either in military or civil life, can be left without supervision. We have seen (p. 69a and c) the P.V.O. left miles behind the army, performing duties which should have been carried out by a subordinate veterinary officer. The Staff has yet to learn that if good veterinary work in the Field is desired the responsible man must be on the spot, and not at the end of a vulnerable telegraph line; that the numbers must be sufficient to exercise effective control over the whole Field. Given these and the means to work with, we shall hear no more of the breakdown of the veterinary service in war. Until then, as in the case of South Africa, we publicly decline to be held responsible for the failure which we earnestly endeavoured to avert.

The small band of executive officers, whose numbers we have mentioned at p. 4c, were good. With few exceptions they were relatively young. The best evidence of their value and usefulness is afforded by the constant struggle occurring for their possession and retention by units. They were, however, a mere drop in the ocean; without making any allowance for sickness or death, the total would not have supplied the veterinary staff subsequently required for Hospitals and Remount Depots alone.

It is sometimes said by those with no practical knowledge of the subject that nothing can be done for the sick, lame and wounded in the fighting line, and that veterinary officers are better placed on the line of communication. This shows an entire misapprehension of the duties of a veterinary officer, and what he is capable of effecting with proper organization. Who, for instance, is the best person to determine whether an animal should leave the fighting line or be sent to Hospital? (See p. 24c). Who is there capable of detecting an outbreak of contagious or infectious disease, and either nipping it in the bud or keeping it under control? Who is capable of examining captured animals and ascertaining their freedom from disease before being utilized in the ranks or elsewhere? What is to

occur to fire, saddle, and other urgent injuries; are these and the treatment of internal diseases to be left to the squadron or battery farrier? An examination of the figures on p. 227b gives some notion of the amount of sickness and injury occurring in the Field.

To hold such a view as the above is practically the complement of the suggested policy that horses should be worked out and then destroyed, for such is what would actually occur. We have seen in these pages the military results of such a system, and the drain it causes on horse supply; it is monstrously expensive, and it is certainly wanting in the elements of humanity. Animals in war have a right to treatment (see p. 41d), quite apart from the fact that when cured they are a potential source of strength, and of more value than a remount.

#### VETERINARY SERVICE OF THE IMPERIAL YEOMANRY.

We have felt throughout this History that the services of the officers of the Imperial Yeomanry, as well as that of all other officers of the Irregular Forces, have received very inadequate notice. This, however, is not due to neglect, but to ignorance of the necessary facts which in a regimental organisation were unknown to those outside. We should really know nothing of this service but for two reports\* published by the Deputy Adjutant-General of the Imperial Yeomanry. In these we are told that it was decided that the veterinary service of this arm should be on a regimental basis. The officers were engaged on contract, and received the pay and allowances of a Veterinary-Lieutenant. Every candidate for appointment should, according to Regulation, have been a qualified practitioner. The D.A.G. tells us these could not be obtained in sufficient numbers, from which we judge that unqualified men were engaged. Nothing, however, is said on this serious point, or as to who determined the relative fitness of those so engaged. No mention is made in the report of the number of officers appointed to the Yeomanry, but we believe it was about thirty, of whom two subsequently died.

As we have seen at p. 305d, the above organisation was doomed to failure. Even had the obsolete regimental system been a workable scheme, there were no administrative officers to conduct it. A good example of this may be taken from the above-mentioned Reports. It was intended to form a Remount Depot near Cape Town at the Imperial Yeomanry Base Depot; the horses arrived, some 2000 in all, which were placed in enclosures, but there was no picketing gear, and no local Kafir labour for the care of the animals. In connection with this depot it was intended to form a veterinary hospital, but there was no establishment for it, and no one to organise. Later, some effort was made to imitate the organisation of "an excellent horse

hospital" belonging to the Regular Forces, which lay close to the I.Y. Depot, but the first efforts were unsatisfactory, for which the D.A.G. Imperial Yeomanry blames the veterinary officer-in-charge; but it seems to have been lost sight of that no civilian suddenly imported into military service could possibly organise a hospital without training and experience. Even then, nothing could be done without the necessary personnel for looking after the sick, and at one time, according to the Report, there were 190 sick and lame horses in this hospital and no men to look after them.

This hospital finally came into the hands of a retired officer of the A.V.D., who was employed on Yeomanry Remount duty, and the D.A.G. notes that a rapid improvement took place. The organisation of a Yeomanry Remount Depot and Veterinary Hospital was shortly swept away, and passed into the hands of the Regular Service.

The D.A.G., in his Report, insists on the importance of a good veterinary hospital. He recognises the necessity of departmental control in the statement that its organisation must be left to an efficient veterinary officer, to whom the needful funds for labour and material should be allotted: but he does not, we think, appear to have fully realised the difficulties in having such a place organised by untrained officers, and without a departmental directing head. There must be not only a clear understanding of requirements, a knowledge of finance and discipline, of where and how to obtain the needful military and technical equipment, forage and rations, but there must also be a knowledge of how to systematise the treatment and management of a large number of sick horses in the Field. This can only be gained by experience previously acquired in a hospital. We think the failure of the officer, of whom the D.A.G. complains by name, is readily understandable; it would have been an extraordinary circumstance had he succeeded.

It was a blunder of the first magnitude to send this arm into the Field with a veterinary service on a regimental basis, and we have seen the results.

#### VETERINARY SERVICE OF THE COLONIAL FORCES.

This also was arranged on a regimental basis, and possessed all the disadvantages which we have pointed out in connection with the Yeomanry organisation.

Opportunity has been taken to place on record at p. 6b, 10b, 47a, an appreciation of the services rendered by the small but well organised Natal Army Veterinary Service, which in distinction to the above, was placed on a departmental basis before the war occurred.

The number of officers serving with the Colonial Forces, South African and Over-sea, is unfortunately unknown, but appears to have been about 55. Their losses are also unknown. This is evidence of how completely their organisation was out of touch with the Veterinary Service of the Regular Forces.

\* Imperial Yeomanry, First Report, dated 15th May, 1901, Parliamentary Paper, Cd. 803.

Imperial Yeomanry, Second Report, dated 1st January, 1903, Supplementary to the above.

#### CIVIL VETERINARY SERVICE.

The shortcomings of a hastily collected, untrained service, for duties requiring a special military training of at least a year, have, from time to time, been dealt with in the pages of this history. We have shown that to turn adrift in the Field some hundreds of civilians imbued with patriotism does not constitute an efficient veterinary service.

With few exceptions, the C.V. Surgeons were all young men, the majority having recently qualified. They were engaged for a year (p. 27d), at the end of which time they were free to re-engage or return home. Those who joined at the beginning of the war received the pay and allowances of a Veterinary Lieutenant, and two months' pay as gratuity on completing the year of service. Towards the end of the year 1900 it was evident this rate of remuneration was insufficient to retain the services of those now experienced. In June, 1901, it was decided that better terms must be offered; an increase in pay of 5/- a day was given after eighteen months' service, and a gratuity of fourteen days' pay for every three months' additional service. A short experience of these terms proved they were not sufficiently attractive to men who were losing time in starting in private practice. In December, 1901, it was approved that the increase of 5/- a day should be given at twelve months' service, and an additional 2/6 after eighteen months' service. These improved terms did not lessen the difficulties, so that in May, 1902, it was decided to offer £1 a day pay for the first year, to be raised to 25/- a day after twelve months' service, and 27/6 after eighteen months' service. How far these terms would have worked had the war continued we cannot say, but £1 a day, and the usual allowances and gratuity, should be the minimum offered to a civilian service which has no claim on the State in the event of an injury, other than that received in action, or impairment of health the result of service in the Field.

The total number of Civil Veterinary Surgeons engaged for the war was 283, of whom seven died during the campaign, and one or more shortly afterwards. The first arrivals occurred at the end of 1899; by the time the war had lasted six months there were 120 civil veterinary surgeons in the Field. The difficulties and disadvantages under which these gentlemen laboured are fully set forth at p. 28a; rank was withheld from them (see p. 48d), though granted to Yeomanry and Colonial veterinary officers, and, in fact, to everyone in the Field excepting Civil Surgeons and Civil Veterinary Surgeons. They possessed no authority (p. 27d), though frequently placed in positions where such was essential to the working of their charge (see pp. 73b and 197d).

It is unnecessary to reiterate their difficulties, they were many and acute. In one respect the regular service failed towards them, and that was in not making sufficient allowance for their ignorance of military matters. We forgot, in the stress of events, the years it had taken us to acquire a working knowledge of the military machine, and often, we fear, expected more than the average civilian could yield. That there were many weak vessels among them goes without saying where no selection was possible, but many of their difficulties would have disappeared had there been administrative officers to whom they could have looked for instruction, instead of being—to use a local expression—"dumped down" on the veldt and left to their own devices. When it is remembered that the average proportion of Civil Veterinary Surgeons to Regular officers was as 4½ to one, it will be seen what a large share of the veterinary duties they were destined to bear.

The Civil Veterinary Service when trained did useful service; some of its members possessed marked ability and did excellent work, as the pages of this History have testified. It took six months to train a first-rate man, the average man took a year, and many were never trained (see p. 28c). This was due in many cases to ineptitude, in others to lack of opportunity, owing to the insignificant number of administrative officers.

The mushroom-like character of the forces used in the war had its reflex in the veterinary service. Regiments were created and disbanded in the course of a few months, and new regiments took their place. Similarly, civil veterinary surgeons, just as they were getting in touch with their work suddenly returned home on expiration of contract, and the whole business of acquiring knowledge by the process of blundering had to be gone through with the new arrivals. Such a system is hopeless as an effective organization. This system of civil veterinary aid in war is absolutely indefensible. Over and over again we have insisted that the Field is not the place to carry out a primary training, no matter for what service the person is intended.

#### THE SEA-TRANSPORT VETERINARY SERVICE.

This has already been dealt with. We have seen, at p. 255b, that the work of the British Veterinary Surgeons gave satisfactory results, but the foreigners engaged by the Remount Department were badly reported upon, and brought great discredit on the British service. The rates of remuneration are dealt with at p. 262b. The difficulties of Transport Veterinary Surgeons at sea are fully recorded at p. 255c *et seq.*, and their equally great difficulties ashore have been illustrated in detail at p. 262d, footnote *et seq.*

## INDEX

The letters after the figures indicate the position on the page where the information will be found. The pages are divided into four roughly equal parts, *a*, *b*, *c*, *d*; the letters follow the text, thus *a* and *b* are in the left column, *c* and *d* in the right.
